TPS25982 2.7-V to 24-V, 2.7mΩ, 15-A Smart eFuse - Integrated Hot-Swap protection with 1.5% Accurate Load Current Monitoring and Adjustable Transient Fault Management

1 Features

- Wide input voltage range: 2.7 V to 24 V
  - 30-V Absolute maximum
- Low On-Resistance: R_{ON} = 2.7-mΩ typical
- Adjustable current limit threshold
  - Range: 2 A to 15 A
  - Accuracy: ± 8% (typical for I_{LIM} > 5 A)
- Circuit breaker and current limiter options
- Adjustable over-current blanking timer
  - Handles load transients without tripping
- Accurate current monitor output
  - ± 1.5% (typical at 25 °C for I_{OUT} > 3 A)
- User configurable fault response
  - Latch-off or auto-retry
  - Number of retries (Finite or indefinite)
  - Delay between retries
- Robust short-circuit protection
  - Fast-trip response time < 400-ns typical
  - Tested against 1 million power-into-short events
  - Immune to line transients - no nuisance tripping
- Adjustable output slew rate (dVdt) control
- Adjustable undervoltage lockout
- Overvoltage lockout (Fixed 3.7-V, 7.6-V, 16.9-V and no-OVLO options)
- Integrated overtemperature protection
- Power good indication
- Adjustable load detect and handshake timer
- UL 2367 Recognition
  - File no. E339631
  - R_{ILIM} ≥ 182 Ω
- IEC 62368 CB Certification
- Small footprint: 4-mm × 4-mm QFN package

2 Applications

- Hot-Swap, hot-plug
- Server standby rail, PCIe riser, add-on card and fan module protection
- Routers and switches optical module protection
- Industrial PC
- Digital TV

3 Description

The TPS25982 family of eFuses is a highly integrated circuit protection and power management solution in a small package. The devices are operational over a wide input voltage range. A single part caters to low-voltage systems needing minimal I*R voltage drop as well as higher voltage, high current systems needing low power dissipation. They are a robust defense against overloads, short-circuits, voltage surges and excessive inrush current.

Overvoltage events are limited by internal cutoff circuits, with multiple device options to choose the overvoltage threshold.

Multiple device options exist to choose between the response to overcurrent conditions, circuit breaker or active current limiter. The overcurrent limit and fast-trip (short-circuit) threshold can be set with a single external resistor. The devices intelligently manage the overcurrent response by distinguishing between transient events and actual faults, thereby allowing the system to function uninterrupted during line and load transients without compromising on the robustness of the protection against faults. The device can be configured to stay latched off or retry automatically after a fault shutdown. The number of auto-retries as well as the retry delay are configurable with capacitors. This enables remote systems to automatically recover from temporary faults while ensuring that power supplies are not stressed indefinitely due to a persistent fault.

The TPS25982 devices are available in a small 4 mm × 4 mm QFN package. The devices are characterized for operation over a junction temperature range of –40˚C to 125˚C.

Device Information(1)

PART NUMBER	PACKAGE	BODY SIZE (NOM)
TPS25982	QFN (24)	4.0 mm × 4.0 mm

Pin Functions

PIN		TYPE	DESCRIPTION
NAME	NO.		
OUT	17, 18, 19, 20, 21, 22, 23, 24	Power	Power Output
IN	1, 2, 3, 16, Pad 1	Thermal / Power	Power Input. The exposed pad must be soldered to input power plane uniformly to ensure proper heat dissipation and to maintain optimal current distribution through the device.
GND	4, 5, 14, Pad 2	Ground	Connect to System Ground
EN/UVLO	6	Analog Input	Active High Enable for the device. A resistor divider on this pin from input supply to GND can be used to adjust the Undervoltage Lockout threshold. **Do not leave floating.**
ITIMER	7	Analog Output	A capacitor from this pin to GND sets the overcurrent blanking interval during which the output current can temporarily exceed set current limit (but lower than fast-trip threshold) before the device overcurrent response takes action. Leave this pin open for fastest response to overcurrent events. Refer to *ITIMER Functional Mode Summary* for more details.
ILIM	8	Analog Output	An external resistor from this pin to GND sets the output current limit threshold and fast trip threshold. **Do not leave floating.**
IMON	9	Analog Output	Analog output load current monitor. This pin sources a current proportional to the load current. This can be converted to a voltage signal by connecting an appropriate resistor from this pin to GND.
RETRY_DLY	10	Analog Output	A capacitor from this pin to GND sets the time period that has to elapse after a fault shutdown before the device attempts to restart automatically. Connect this pin to GND for latch-off operation (no auto-retries) after a fault. Refer to *Fault Response* section for more details.
NRETRY	11	Analog Output	A capacitor from this pin to GND sets the number of times the part attempts to restart automatically after shutdown due to fault. Connect this pin to GND if the part should retry indefinitely. Refer to *Fault Response* section for more details.

Pin Functions (continued)

PIN		TYPE	DESCRIPTION
NAME	NO.		
LDSTRT	12	Analog Input	Load Detect/Handshake Signal. A capacitor from this pin to GND sets the time period after PG assertion within which the pin has to be pulled low for the device to remain ON. Connect to GND if the load detect/handshake feature is not used. Refer to *Load Detect/Handshake (LDSTRT)* section for more details. **Do not leave floating.**
PG	13	Digital Output	Active High Power Good Indication. This pin is asserted when the FET is fully enhanced and output has reached maximum voltage. It is an open drain output that requires an external pull-up resistor to an external supply. This pin remains logic low when $V_{IN} < V_{UVP}$.
dVdt	15	Analog Output	A capacitor from this pin to GND sets the output turn on slew rate. Leave this pin floating for the fastest slew rate during start up.

7 Specifications

7.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)(1)

Parameter		Pin	MIN	MAX	UNIT
V_{IN}	Maximum Input Voltage Range	IN	–0.3	30	V
V_{OUT}	Maximum Output Voltage Range	OUT	–0.8	min (30V, V_{IN} + 0.3)	V
$V_{EN/UVLO}$	Maximum Enable Pin Voltage Range	EN/UVLO	–0.3	7	V
V_{LDSTRT}	Maximum LDSTRT Pin Voltage Range	LDSTRT		7	V
V_{dVdt}	Maximum dVdt Pin Voltage Range	dVdt	Internally Limited		V
V_{PG}	Maximum PG Pin Voltage Range	PG	–0.3	7	V
V_{ITIMER}	Maximum ITIMER Pin Voltage Range	ITIMER	Internally Limited		V
V_{NRETRY}	Maximum NRETRY Pin Voltage Range	NRETRY	Internally Limited		V
V_{RETRY_DLY}	Maximum RETRY_DLY Pin Voltage Range	RETRY_DLY	Internally Limited		V
I_{MAX}	Maximum Continuous Switch Current	IN to OUT	Internally Limited		A
T_J	Junction temperature		Internally Limited		°C
T_{LEAD}	Maximum Soldering Temperature			300	°C
T_{stg}	Storage temperature		–65	150	°C

(1) Stresses beyond those listed under *Absolute Maximum Rating* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

7.2 ESD Ratings

			VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001, all pins(1)	± 2000	V
		Charged device model (CDM), per JEDEC specificationJESD22-C101, all pins(2)	± 1000	

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

7.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

Parameter		Pin	MIN	MAX	UNIT
V_{IN}	Input Voltage Range	IN	2.7	24	V
V_{OUT}	Output Voltage Range	OUT		V_{IN} + 0.3	V
$V_{EN/UVLO}$	Enable Pin Voltage Range	EN/UVLO		6 (1)	V
V_{LDSTRT}	LDSTRT Pin Capacitor Voltage Rating	LDSTRT	4		V
V_{dVdT}	dVdT Pin Capacitor Voltage Rating	dVdt	V_{IN} + 4		V
V_{PG}	PG Pin Voltage Range	PG		6 (2)	V
V_{ITIMER}	ITIMER Pin Capacitor Voltage Rating	ITIMER	4		V
V_{NRETRY}	NRETRY Pin Capacitor Voltage Rating	NRETRY	4		V
V_{RETRY_DLY}	RETRY_DLY Pin Capacitor Voltage Rating	RETRY_DLY	4		V
R_{ILIM}	ILIM Pin Resistor	ILIM	82	1650	Ω
I_{MAX}	Continuous Switch Current	IN to OUT		15	A
T_J	Junction temperature		–40	125	°C

(1) For supply voltages below 6V, it is okay to pull up the EN pin to IN directly. For supply voltages greater than 6V, it is recommended to use an appropriate resistor divider between IN, EN and GND to ensure the voltage at the EN pin is within the specified limits.
(2) For supply voltages below 6V, it is okay to pull up the PG pin to IN/OUT through a resistor. For supply voltages greater than 6V, it is recommended to use a stepped down power supply to ensure the voltage at the PG pin is within the specified limits.

7.4 Thermal Information

THERMAL METRIC (1) (2)		TPS25982X RGE (QFN) 24 PINS	UNIT
$R_{\theta JA}$	Junction-to-ambient thermal resistance	34.6	°C/W
$R_{\theta JC(top)}$	Junction-to-case (top) thermal resistance	36.7	°C/W
$R_{\theta JB}$	Junction-to-board thermal resistance	11.2	°C/W
Ψ_{JT}	Junction-to-top characterization parameter	3	°C/W
Ψ_{JB}	Junction-to-board characterization parameter	11.2	°C/W
$R_{\theta JC(bot)}$	Junction-to-case (bottom) thermal resistance	1.6	°C/W

(1) For more information about traditional and new thermal metrics, see the Semiconductor and IC Package Thermal Metrics application report.
(2) Based on simulations conducted with the device mounted on a JEDEC 4-layer PCB (2s2p) with minimum recommended pad size (2 oz Cu) and 3x2 via array.

7.5 Electrical Characteristics

(Test conditions unless otherwise noted) –40°C ≤ T_J ≤ 125°C, V_{IN} = 12 V for TPS259824x/7x, 5 V for TPS259823x, 3.3 V for TPS259822x, $V_{EN/UVLO}$ = 2 V, R_{ILIM} = 1650 Ω , C_{dVdT} = Open, OUT = Open. All voltages referenced to GND.

7.7 Switching Characteristics

The output rising slew rate is internally controlled and constant across the entire operating voltage range to ensure the turn on timing is not affected by the load conditions. The rising slew rate can be adjusted by adding capacitance from the dVdt pin to ground. As C_{dVdt} is increased it will slow the rising slew rate (SR). See Slew Rate and Inrush Current Control (dVdt) section for more details. The Turn-Off Delay and Fall Time, however, are dependent on the RC time constant of the load capacitance (C_{OUT}) and Load Resistance (R_L). The Switching Characteristics are only valid for the power-up sequence where the supply is available in steady state condition and the load voltage is completely discharged before the device is enabled.Typical Values are taken at T_J = 25°C unless specifically noted otherwise. R_L = 3.6 Ω, C_{OUT} = 1 mF

PARAMETER		V_{IN}	C_{dVdt} = Open	C_{dVdt} = 3300pF	C_{dVdt} = 6800pF	UNIT
SR_{ON}	Output Rising slew rate	2.7 V	6.26	1.39	0.68	V/ms

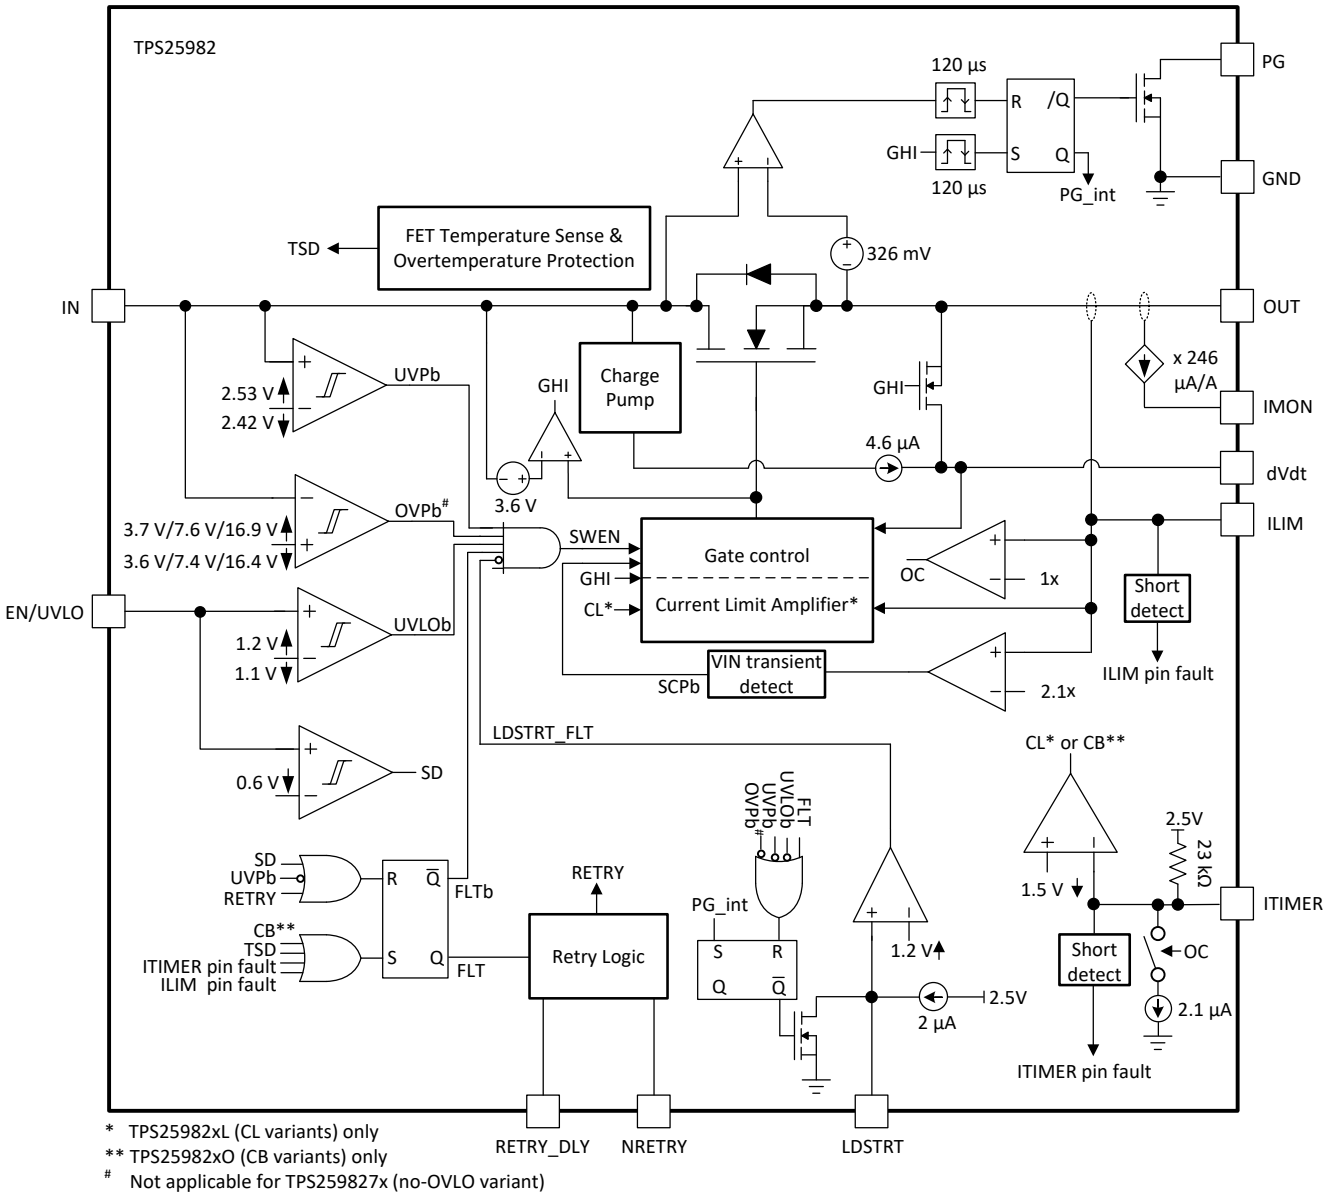
8 Detailed Description

8.1 Overview

The TPS25982 device is a smart eFuse with integrated power switch that is used to manage load voltage and load current. The device starts its operation by monitoring the IN bus. When V_{IN} is above the Undervoltage Protection threshold (V_{UVP}) and below the Overvoltage Protection threshold (V_{OVP}), the device samples the EN/UVLO pin. A high level on this pin enables the internal MOSFET to start conducting and allow current to flow from IN to OUT. When EN/UVLO is held low, the internal MOSFET is turned off. After a successful start-up sequence, the device now actively monitors its load current, input voltage and protects the load from harmful overcurrent and overvoltage conditions. The device also relies on a built-in thermal sense circuit to shut down and protect itself in case the device internal temperature (T_j) exceeds the safe operating conditions.

8.2 Functional Block Diagram



* TPS25982xL (CL variants) only
** TPS25982xO (CB variants) only
\# Not applicable for TPS259827x (no-OVLO variant)

8.3 Feature Description

The TPS25982 eFuse is a compact, feature rich power management device that provides detection, protection and indication in the event of system faults.

8.3.1 Undervoltage Protection (UVLO and UVP)

The TPS25982 implements Undervoltage Protection on IN to turn off the output in case the applied voltage becomes too low for the downstream load or the device to operate correctly. The Undervoltage Protection has a default internal threshold of V_{UVP}. If needed, it is also possible to set a user defined Undervoltage Protection threshold higher than V_{UVP} using the UVLO comparator on the EN/UVLO pin. Figure 42 and Equation 1 show how a resistor divider from supply to GND can be used to set the UVLO set point for a given voltage supply level.

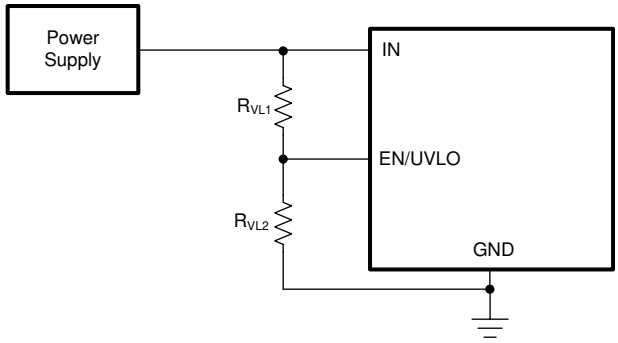


Figure 42. Adjustable Supply UVLO Threshold

$$VIN_{UVLO} = \frac{V_{UVLO(R)} \times (R_{VL1} + R_{VL2})}{R_{VL2}} \quad (1)$$

The resistors must be sized large enough to minimize the constant leakage from supply to ground through the resistor divider network. At the same time, keep the current through the resistor network sufficiently larger (20x) than the leakage current on the EN/UVLO pin to minimize the error in the resistor divider ratio.

8.3.2 Overvoltage Protection (OVP)

The TPS25982 implements Overvoltage Lock-Out (OVLO) on IN to protect the output load in the event of input overvoltage. When the input exceeds the Overvoltage Protection threshold ($V_{OVP(R)}$) the device turns off the output within t_{OVP}. As long as an overvoltage condition is present on the input, the device stays disabled and the output will be turned off. Once the input voltage returns to the normal operating range, the device attempts to start up normally.

Feature Description (continued)

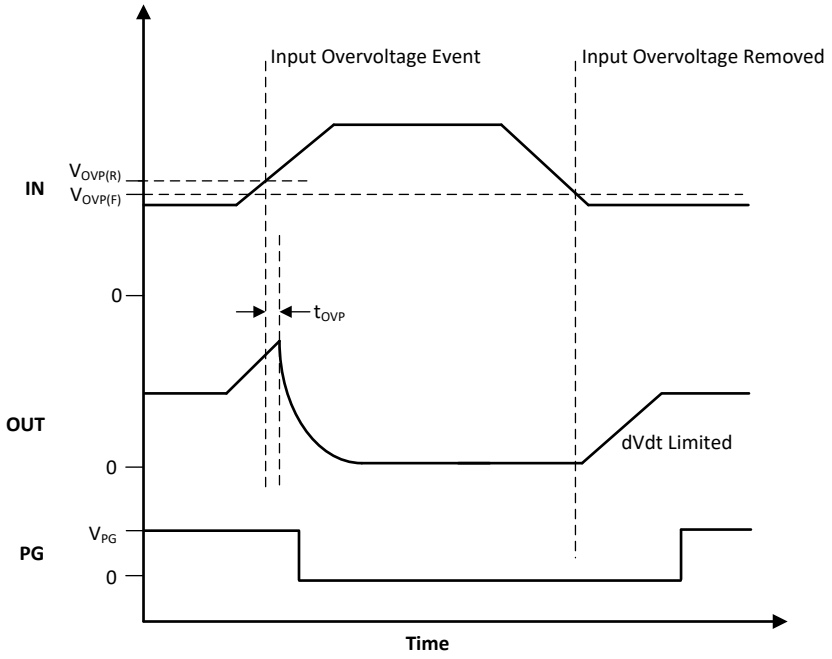

Figure 43. Overvoltage Response

There are multiple device options with different fixed overvoltage thresholds to choose from, including one without internal overvoltage protection. See the *Device Comparison Table* for a list of available options.

8.3.3 Inrush Current, Overcurrent, and Short-Circuit Protection

TPS25982 devices incorporate three levels of protection against overcurrent:

- Adjustable slew rate (dVdt) for inrush current control
- Adjustable overcurrent protection (with adjustable blanking timer) - Circuit Breaker or Active Current Limiter to protect against soft overload conditions
- Adjustable fast-trip response to quickly protect against severe overcurrent (short-circuit) faults

8.3.3.1 Slew Rate and Inrush Current Control (dVdt)

During hot-plug events or while trying to charge a large output capacitance, there can be a large inrush current. If the inrush current is not controlled, it can damage the input connectors and/or cause the system power supply to droop leading to unexpected restarts elsewhere in the system. The TPS25982 provides integrated output slew rate (dVdt) control to manage the inrush current during start-up. The inrush current is directly proportional to the load capacitance and rising slew rate. The following equation can be used to calculate the slew rate (SR) required to limit the inrush current (I_{INRUSH}) for a given load capacitance (C_{OUT}):

$$SR\left(V/ms\right) = \frac{I_{INRUSH}(mA)}{C_{OUT}(\mu F)} \tag{2}$$

An external capacitance can be connected to the dVdt pin to control the rising slew rate and lower the inrush current during turn on. The required C_{dVdt} capacitance to produce a given slew rate can be calculated using the following formula:

$$C_{dVdt}\left(pF\right) = \frac{4600}{SR\left(V/ms\right)} \tag{3}$$

The fastest output slew rate is achieved by leaving the dVdt pin open.

Feature Description (continued)

8.3.3.2 Circuit Breaker

The TPS25982xO (Circuit Breaker) variants respond to output overcurrent conditions by turning off the output after a user adjustable transient fault blanking interval. When the load current exceeds the programmed current limit threshold (I_{LIM} set by the ILIM pin resistor R_{ILIM}), but lower than the fast-trip threshold (2.1 x I_{LIM}), the device starts discharging the ITIMER pin capacitor using an internal pull-down current (I_{ITIMER}). If the load current drops below the current limit threshold before the ITIMER capacitor drops by ΔV_{ITIMER}, the circuit breaker action is not engaged and the ITIMER is reset by pulling it up to V_{INT} internally. This allows short transient overcurrent pulses to pass through the device without tripping the circuit. If the overcurrent condition persists, the ITIMER capacitor continues to discharge and once it falls by ΔV_{ITIMER}, the circuit breaker action turns off the FET immediately. The following equation can be used to calculate the R_{ILIM} value for a desired current limit threshold.

$$R_{ILIM}(\Omega) = \frac{1460}{I_{LIM}(A) - 0.11} \quad (4)$$

NOTE

Leaving the ILIM pin Open sets the current limit to zero and causes the FET to shut off as soon as any load current is detected. Shorting the ILIM pin to ground at any point during normal operation is detected as a fault and the part shuts down. The ILIM pin Short to GND fault detection circuit requires a minimum amount of load current (I_{CB}) to flow through the device. This ensures robust eFuse behavior even under single point failure conditions. Refer to the *Fault Response* section for details on the device behavior after a fault.

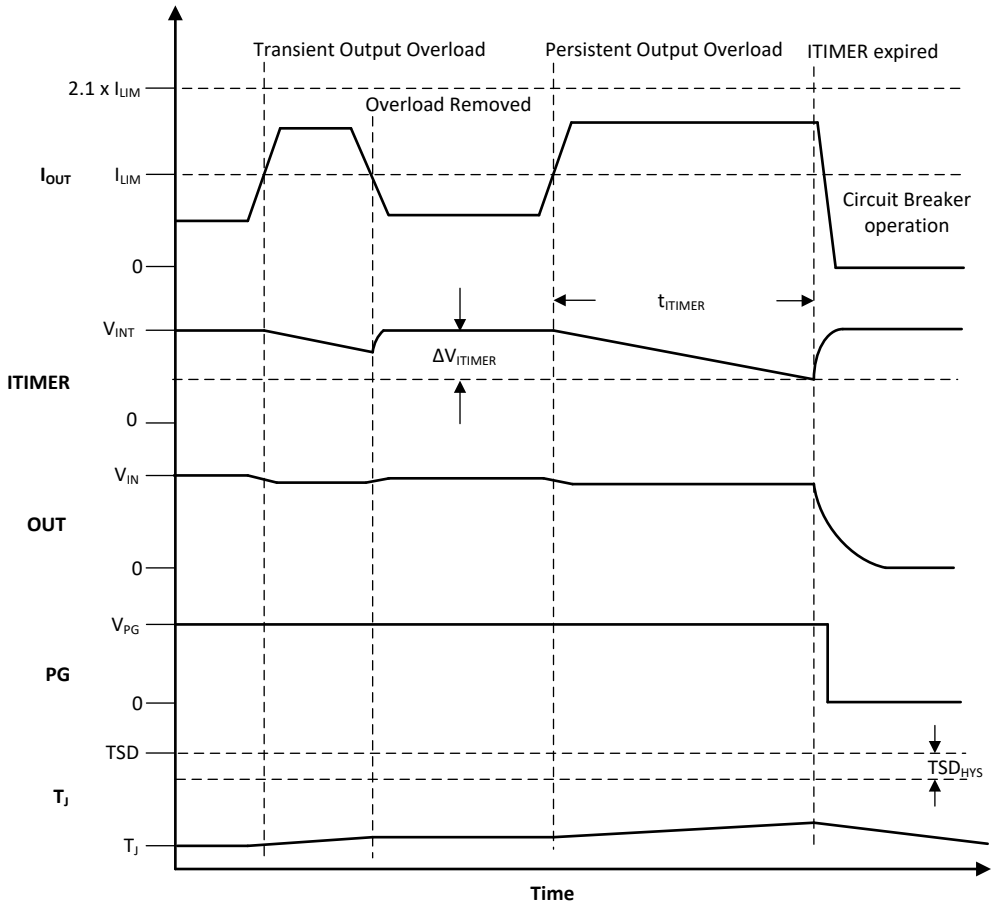

Figure 44. Circuit Breaker Response

Feature Description (continued)

The duration for which load transients are allowed can be adjusted using an appropriate capacitor value from ITIMER pin to ground. The transient overcurrent blanking interval can be calculated using Equation 5.

$$t_{ITIMER}\,(ms) = \frac{C_{ITIMER}\,(nF) \times \Delta V_{ITIMER}\,(V)}{I_{ITIMER}\,(\mu A)} \quad (5)$$

Leave the ITIMER pin open to allow the part to break the circuit with the minimum possible delay.

Table 1. Device ITIMER Functional Mode Summary

ITIMER Pin Connection	Timer Delay before Overcurrent response
OPEN	0 s
Capacitor to ground	As per Equation 5
Short to GND	ITIMER Pin Fault - Part Shuts Off

NOTE

1. Shorting the ITIMER pin to ground is detected as a fault and the part shuts down. This ensures robust eFuse behavior even in case of single point failure conditions. Refer to the *Fault Response* section for details on the device behavior after a fault.

2. Larger ITIMER capacitors take longer to charge during start-up and may lead to incorrect fault assertion if the ITIMER voltage is still below the pin short detection threshold after the device has reached steady state. To avoid this, it is recommended to limit the maximum ITIMER capacitor to the value suggested by the equation below.

$$C_{ITIMER} < \frac{t_{GHI}}{53000}$$

$$t_{GHI} = t_{D,ON} + C_{dvdt} \times \left(\frac{V_{IN} + 3.6V}{I_{dvdt}} \right)$$

Where

- t_{GHI} is the time taken by the device to reach steady state
- $t_{D,ON}$ is the device turn-on delay
- C_{dvdt} is the dVdt capacitance
- I_{dvdt} is the dVdt charging current

It is possible to avoid incorrect ITIMER pin fault assertion and achieve higher ITIMER intervals if needed by increasing the dVdt capacitor value accordingly, but at the expense of higher start-up time.

Once the part shuts down due to a Circuit Breaker fault, it can be configured to either stay latched off or restart automatically. Refer to the *Fault Response* section for details.

8.3.3.3 Active Current Limiting

The TPS25982xL (Current Limiter) variants respond to output overcurrent conditions by actively regulating the current to a set limit after a user adjustable fault blanking interval. When the load current exceeds the programmed current limit threshold (I_{LIM} set by the ILIM pin resistor R_{ILIM}), but lower than the fast-trip threshold (2.1 x I_{LIM}), the device starts discharging the ITIMER pin capacitor using an internal pull-down current (I_{ITIMER}). If the load current drops below the current limit threshold before the ITIMER capacitor voltage drops by ΔV_{ITIMER}, the current limit action is not engaged and the ITIMER is reset by pulling it up to V_{INT} internally. This allows short transient overcurrent pulses to pass through the device without limiting the current. If the overcurrent condition persists, the ITIMER capacitor continues to discharge and once it falls by ΔV_{ITIMER}, the device regulates the FET gate voltage to actively limit the output current to the set I_{LIM} level. The device will exit current limiting when the load current falls below I_{LIM}. Equation 6 can be used to calculate the R_{ILIM} value for a desired current limit.

$$R_{ILIM}(\Omega) = \frac{1460}{I_{LIM(A)} - 0.11} \quad (6)$$

NOTE

Leaving the ILIM pin Open sets the current limit to zero and causes the FET to shut off as soon as any load current is detected. Shorting the ILIM pin to ground at any point during normal operation is detected as a fault and the part shuts down. The ILIM pin Short to GND fault detection circuit requires a minimum amount of load current (I_{CB}) to flow through the device. This ensures robust eFuse behavior even under single point failure conditions. Refer to the *Fault Response* section for details on the device behavior after a fault.

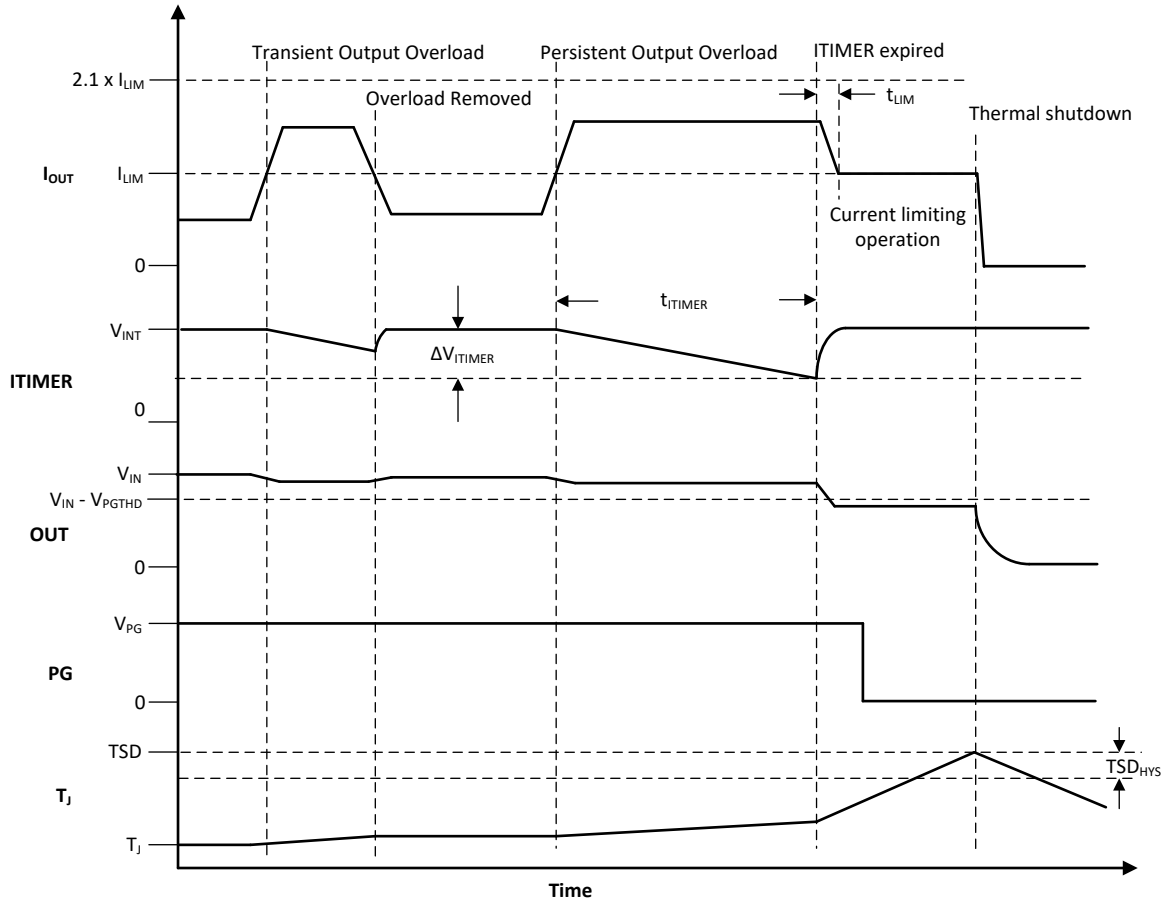

Figure 45. Active Current Limiter Response

The duration for which load transients are allowed can be adjusted using an appropriate capacitor value from ITIMER pin to ground. The transient overcurrent blanking interval can be calculated using Equation 7.

$$t_{ITIMER}\,(ms) = \frac{C_{ITIMER}\,(nF) \times \Delta V_{ITIMER}\,(V)}{I_{ITIMER}\,(\mu A)} \quad (7)$$

Leave the ITIMER pin open to allow the part to activate the current limit with the minimum possible delay. Refer to *ITIMER Functional Mode Summary* for more details.

NOTE

1. Current limiting based on R_{ILIM} is active during startup for both Current Limit and Circuit Breaker variants. In case the startup current exceeds I_{LIM}, the device regulates the current to the set limit. However, during startup the current limit is engaged without waiting for the ITIMER delay.

2. Shorting the ITIMER pin to ground is detected as a fault and the part shuts down. This ensures robust eFuse behavior even in case of single point failure conditions. Refer to the *Fault Response* section for details on the device behavior after a fault.

3. Larger ITIMER capacitors take longer to charge during start-up and may lead to incorrect fault assertion if the ITIMER voltage is still below the pin short detection threshold after the device has reached steady state. To avoid this, it is recommended to limit the maximum ITIMER capacitor to the value suggested by the equation below.

$$C_{ITIMER} < \frac{t_{GHI}}{53000}$$

$$t_{GHI} = t_{D,ON} + C_{dvdt} \times \left(\frac{V_{IN} + 3.6V}{I_{dvdt}} \right)$$

Where

- t_{GHI} is the time taken by the device to reach steady state
- $t_{D,ON}$ is the device turn-on delay
- C_{dvdt} is the dVdt capacitance
- I_{dvdt} is the dVdt charging current

It is possible to avoid incorrect ITIMER pin fault assertion and achieve higher ITIMER intervals if needed by increasing the dVdt capacitor value accordingly, but at the expense of higher start-up time.

During current regulation, the output voltage will drop resulting in increased device power dissipation across the FET. If the device internal temperature (T_J) exceeds the thermal shutdown threshold (TSD), the FET is turned off. See *Overtemperature Protection (OTP)* for more details on device response to overtemperature.

8.3.3.4 Short-Circuit Protection

During an output short-circuit event, the current through the device increases very rapidly. When an output short-circuit is detected, the internal fast-trip comparator turns off the output within the t_{SC}. The comparator employs a scalable threshold which is equal to 2.1 × I_{LIM}. This enables the user to adjust the fast-trip threshold as per system needs rather than using a fixed threshold which may not be suitable for all systems. After a fast trip event, the device restarts in a current limited mode to try and restore power to the load quickly in case the fast trip was triggered by a transient event. However, if the fault is persistent, the device will stay in current limit causing the junction temperature to rise and eventually enter thermal shutdown. See *Overtemperature Protection (OTP)* section for details on the device response to overtemperature.

In some of the systems, for example servers or telecom equipment which house multiple hot-pluggable cards connected to a common supply backplane, there can be transients on the supply due to switching of large currents through the inductive backplane. This can result in current spikes on adjacent cards which could be potentially large enough to inadvertently trigger the fast-trip comparator of the eFuse. The TPS25982 uses a proprietary algorithm to avoid nuisance tripping in such cases thereby facilitating un-interrupted system operation.

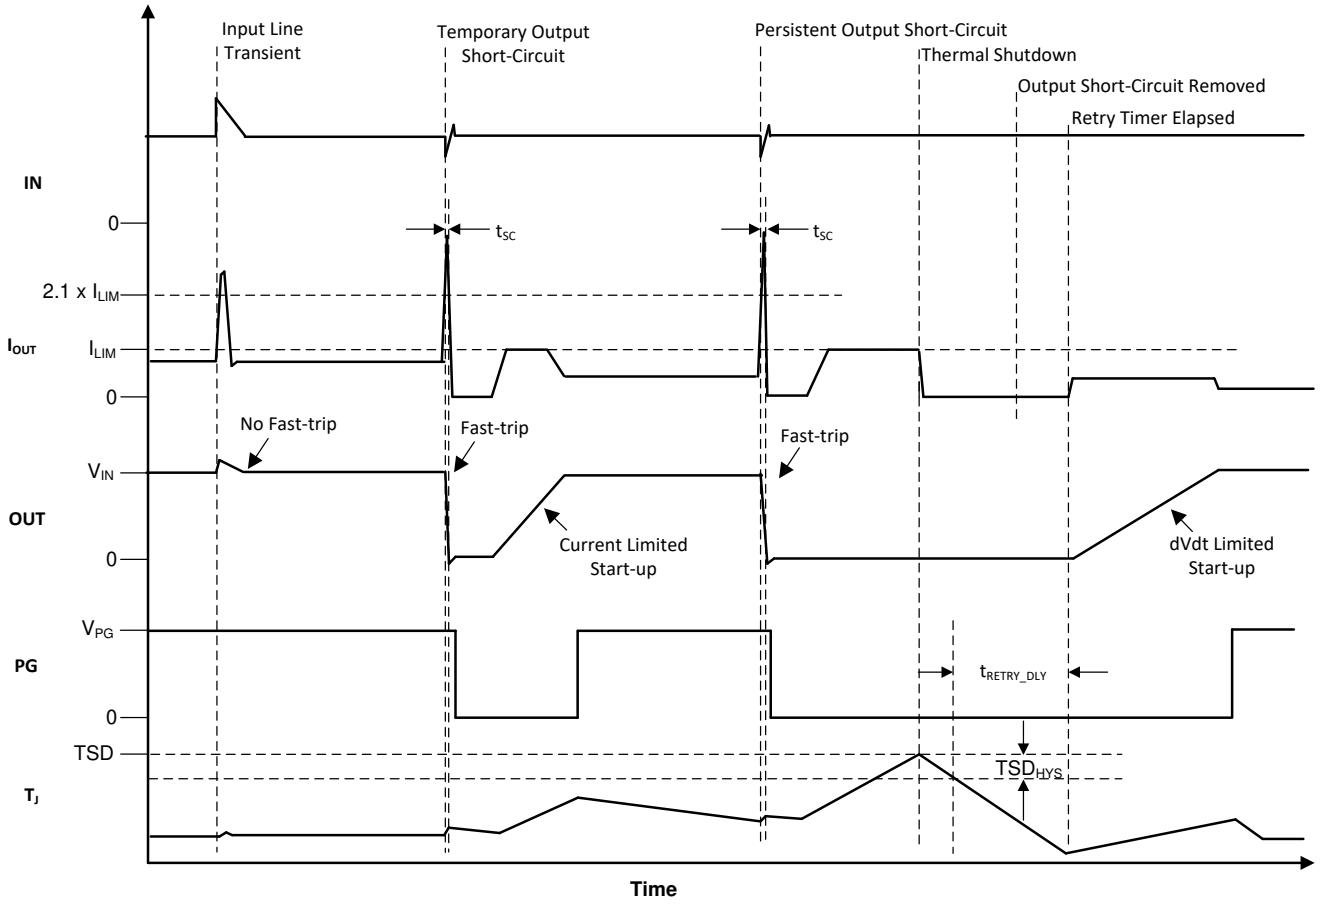

Figure 46. Input Line Transient and Output Short-Circuit Response

NOTE

To prevent the current limit/circuit breaker loop from interfering with the input line transient detection logic, TI recommends to set the ITIMER interval higher than 100 µs. Refer to *Table 1* for more details on ITIMER.

8.3.4 Overtemperature Protection (OTP)

The device monitors the internal die temperature (T_J) at all times and shuts down the part as soon as the temperature exceeds a safe operating level (TSD) thereby protecting the device from damage. The device will not turn back on until the die cools down sufficiently, that is the die temperature falls below (TSD - TSDHys). Thereafter, the part can be configured to either remain latched off or restart automatically. Refer to the *Fault Response* section for details.

8.3.5 Analog Load Current Monitor (IMON)

The device allows the system to monitor the output load current accurately by providing an analog current on the IMON pin which is proportional to the current through the FET. The user can connect a resistor from IMON to ground to convert this signal to a voltage which can be fed to the input of an Analog-to-Digital Converter. The internal amplifier on the IMON employs chopper based offset cancellation techniques to provide accurate measurement even at lower currents over time and temperature.

$$V_{IMON}(V) = G_{IMON}(\mu A / A) \times I_{OUT}(A) \times R_{IMON}(\Omega) \quad (8)$$

It is recommended to limit the maximum IMON voltage to the values mentioned in *VIMON(Max) Recommended Values* . This is to ensure the IMON pin internal amplifier has sufficient headroom to operate linearly.

Table 2. $V_{IMON(MAX)}$ Recommended Values

V_{IN}	Recommended $V_{IMON(MAX)}$
2.7 V	1 V
3.3 V	1.8 V
> 5 V	3.3 V

It is recommended to add a RC low pass filter on the IMON output to filter out any glitches and get a smooth average current measurement. TI recommends a series resistance of 10 kΩ or higher.

8.3.6 Power Good (PG)

PG is an active high open drain output which indicates whether the FET is fully turned ON and the output voltage has reached the maximum value. After power-up, PG is pulled low initially. The gate driver circuit starts charging the gate capacitance from the internal charge pump. When the FET gate voltage reaches (V_{IN} + 3.6V), PG is asserted after a de-glitch time (t_{PGD}). During normal operation, if at any time V_{OUT} falls below (V_{IN} - V_{PGTHD}), PG is de-asserted after a de-glitch time (t_{PGD}).

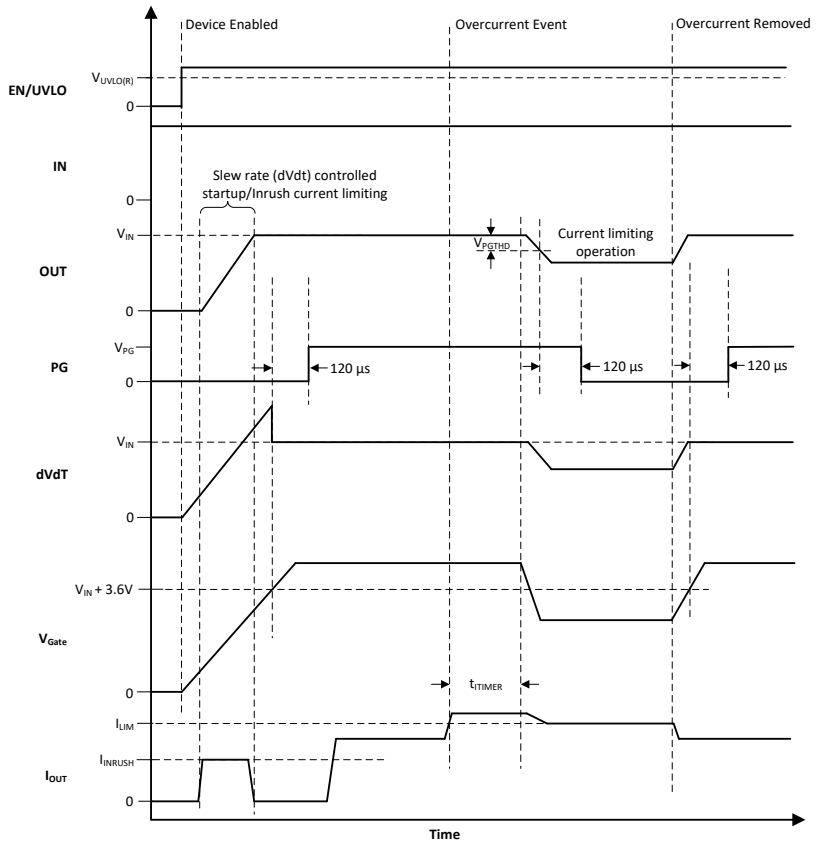

Figure 47. Power Good Assertion and De-assertion

NOTE

1. When there is no supply to the device, the PG pin is expected to stay low. However, there is no active pull-down in this condition to drive this pin all the way down to 0 V. If the PG pin is pulled up to an independent supply which is present even if the TPS25982 is unpowered, there can be a small voltage seen on this pin depending on the pin sink current, which in turn is a function of the pull-up supply voltage and resistor. Minimize the sink current to keep this pin voltage low enough not to be detected as a logic HIGH by associated external circuits in this condition.

2. The PG pin provides a mechanism to detect a possible failed MOSFET condition during start-up. If the PG does not get asserted for an extended period of time after the device is powered up and enabled, it might be an indication of internal MOSFET failure.

8.3.7 Load Detect/Handshake (LDSTRT)

The LDSTRT pin provides a mechanism for the downstream load circuit to indicate to the TPS25982 that the load is present and has powered up successfully. This allows the system to have additional control over the conditions in which power is presented to the load and disconnect the power when the load is not present or unable to provide a valid handshake signal after an expected boot-up time.

Once the TPS25982 completes the startup sequence and the output reaches the full voltage, it asserts the PG signal. At the same time, it also starts charging the capacitor on the LDSTRT pin (C_{LDSTRT}) with an internal current source (I_{LDSTRT}). If the LDSTRT pin voltage rises above V_{LDSTRT} before the load circuit pulls it low, the TPS25982 detects the condition as a LDSTRT fault and turns off the FET to power down the load. The time to trigger the LDSTRT fault can be calculated from the following equation:

$$t_{LDSTRT}\,(ms) = \frac{C_{LDSTRT}\,(nF) \times V_{LDSTRT}\,(V)}{I_{LDSTRT}\,(\mu A)} \tag{9}$$

During normal operation, if at any time the load circuit releases the active pull-down on the LDSTRT pin, the capacitor C_{LDSTRT} would start charging up again and eventually trigger a shutdown due to LDSTRT fault once the capacitor charges up to V_{LDSTRT}.

Once the TPS25982 turns off due to LDSTRT fault, it can be turned ON again in 3 ways:

- LDSTRT pin is driven low
- Input supply voltage is driven low (< $V_{UVP(F)}$) and then driven high (> $V_{UVP(R)}$)
- EN/UVLO voltage is driven low (< V_{SD}) and then driven high (> $V_{UVLO(R)}$)

Tie the LDSTRT pin to ground if this functionality is not needed.

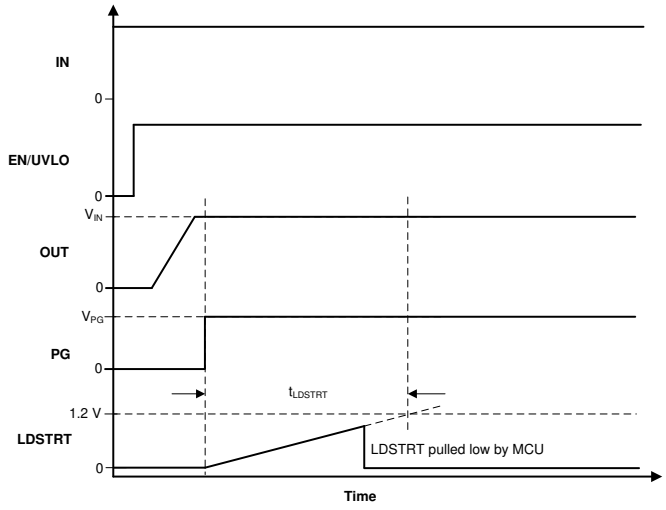

Figure 48. Successful LDSTRT Handshake

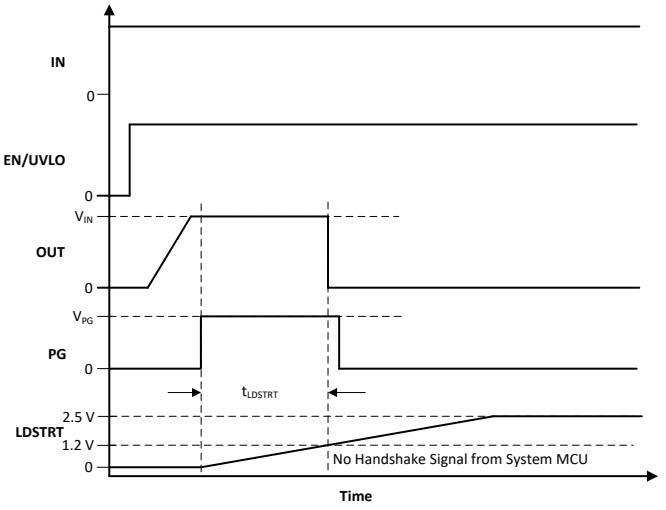

Figure 49. Unsuccessful LDSTRT Handshake

The LDSTRT pin can also be used to implement a load or module detect function wherein the output power is presented only when the load or module is plugged in. A typical use case for this function is on optical module power supply rails in Switches/Routers or similar networking end equipment. The LDSTRT pin should be tied to a corresponding pin on the module connector which gets pulled low by the module when it is plugged in. An example of such a signal is ModPrsL on QSFP-DD modules.

In this scheme, initially when the TPS25982 is powered up or enabled, the output charges up and PG is asserted. If the module is not plugged in, there is no external pull-down on the LDSTRT pin and the pin voltage starts rising due to internal pull-up . Once the LDSTRT pin voltage exceeds V_{LDSTRT}, the TPS25982 turns off the output power. If the module is plugged in later, the LDSTRT pin is pulled low by the module and the TPS25982 turns on the output power.

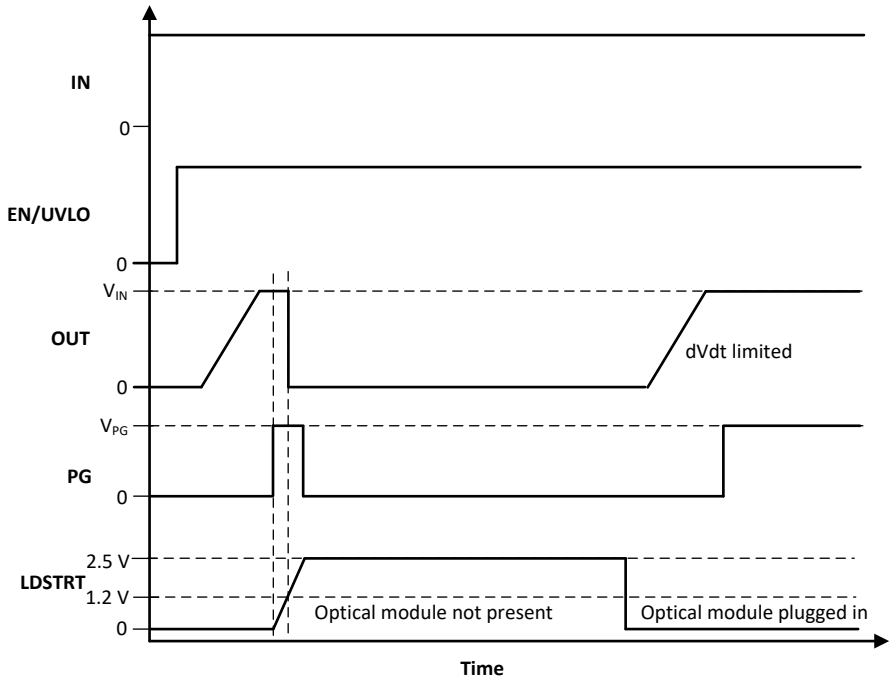

Figure 50. Optical Module Plug-In Detection Using LDSTRT

8.4 Fault Response

The following events trigger an internal fault which causes the device to shut down:

- Overtemperature Protection
- Circuit Breaker Operation
- ITIMER pin Short to GND
- ILIM pin Short to GND

Once the device shuts down due to a fault, even if the associated external fault is subsequently cleared, the fault stays latched internally and the output cannot turn on again until the latch is reset. The fault latch can be externally reset by one of the following methods:

- Input supply voltage is driven low (< $V_{UVP(F)}$)
- EN/UVLO voltage is driven low (< V_{SD})

The fault latch can also be reset by an internal auto-retry logic. The user can either disable the auto-retry behavior completely (latch-off behavior) or configure the device to auto-retry indefinitely or for a limited number of times before latching off. The auto-retry behavior is controlled by the connections on the RETRY_DLY and NRETRY pins.

Fault Response (continued)

Table 3. Pin Configurable Fault Response

EN/UVLO	RETRY_DLY	NRETRY	DEVICE STATE
L	X	X	Disabled
H	Short to GND	X	No auto-retry (Latch-off)
H	Open	Open	Auto-retry 4 times with minimum delay between retries and then latch-off
H	Open	Short to GND	Auto-retry indefinitely with minimum delay between retries
H	Capacitor to GND	Capacitor to GND	Auto-retry delay and count as per Equation 10 and Equation 11
H	Capacitor to GND	Open	Auto-retry 4 times with finite delay between retries as per Equation 10 and then latch-off
H	Capacitor to GND	Short to GND	Auto-retry indefinitely with finite delay between retries as per Equation 10

To configure the part for a finite number of auto-retries with a finite auto-retry delay, first choose the capacitor value on RETRY_DLY pin using the following equation.

$$t_{RETRY\_DLY}\,(\mu s) = \frac{128 \times \left(C_{RETRY\_DLY}\,(pF) + 4\ pF\right) \times V_{RETRY\_DLY\_HYS}\,(V)}{I_{RETRY\_DLY}\,(\mu A)} \quad (10)$$

Next, choose the capacitor value on the NRETRY pin using the following equation.

$$N_{RETRY} = \frac{4 \times I_{RETRY\_DLY}\,(\mu A) \times C_{NRETRY}\,(pF)}{I_{NRETRY}\,(\mu A) \times \left(C_{RETRY\_DLY}\,(pF) + 4\ pF\right)} \quad (11)$$

The number of auto-retries is quantized to certain discrete levels as shown in Table 4 .

Table 4. NRETRY Quantization Levels

NRETRY Calculated From Equation 11	NRETRY Actual
0 < N < 4	4
4 < N < 16	16
16 < N < 64	64
64 < N < 256	256
256 < N < 1024	1024

Table 5. NRETRY and RETRY_DLY Combination Examples

Auto Retry Delay	915 ms	416 ms	91.7 ms	9.3 ms	3 ms
RETRY_DLY Capacitor	22 nF	10 nF	2.2 nF	220 pF	68 pF
No. of Auto Retries	**NRETRY Capacitor**				
4	Open				
16	47 nF	22 nF	4.7 nF	1 nF	220 pF
64	0.22 µF	0.1 µF	22 nF	2.2 nF	1 nF
256	1 µF	0.47 µF	0.1 µF	10 nF	4.7 nF
1024	3.3 µF	1.5 µF	0.47 µF	33 nF	10 nF
Infinite	Short to GND				

A spreadsheet design tool *TPS25982xx Design Calculator* is also available for simplified calculations.

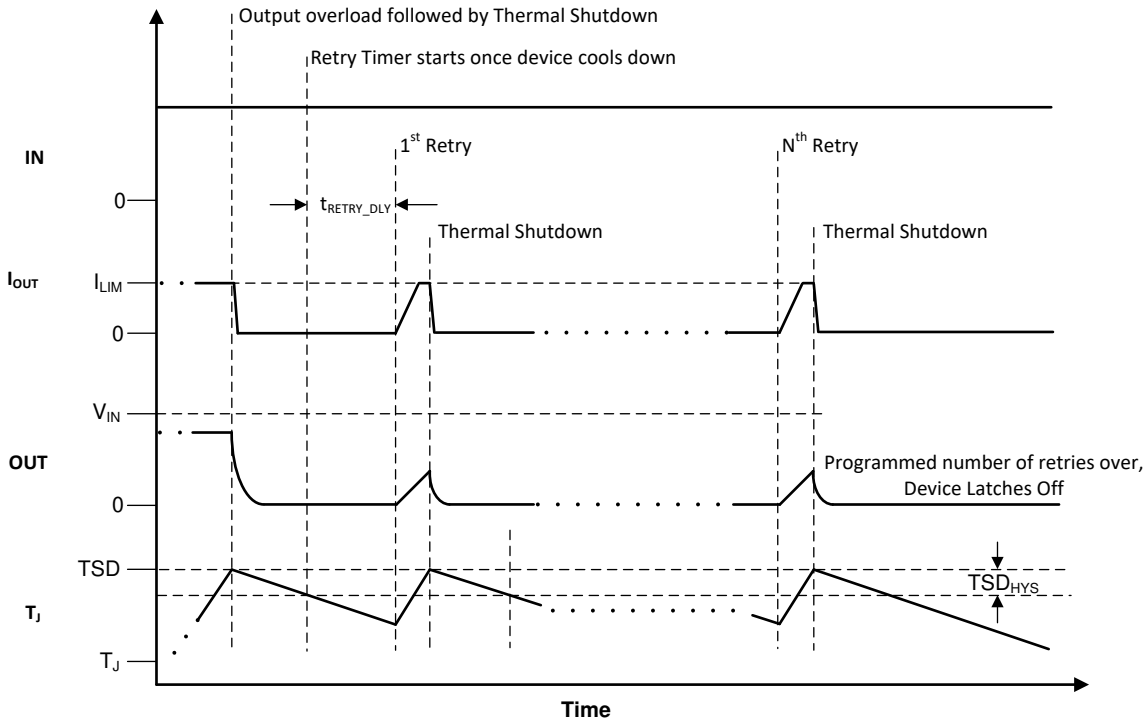

Figure 51. Auto-Retry After Fault

The auto-retry logic has a mechanism to reset the count to zero if two consecutive faults occur far apart in time. This ensures that the auto-retry response to any later fault is handled as a fresh sequence and not as a continuation of the previous fault. If the fault which triggered the shutdown and subsequent auto-retry cycle is cleared eventually and does not occur again for a duration equal to 7 retry delay timer periods starting from the last fault, the auto-retry logic resets the internal auto-retry count to zero.

8.5 Device Functional Modes

The TPS25982 can be pin strapped to support various configurable functional modes.

Table 6. LDSTRT Handshake Functional Modes

EN/UVLO	LDSTRT	DEVICE STATE
L	X	Disabled
H	L	ON
H	H	OFF

Refer to *Load Detect/Handshake (LDSTRT)* section for more details.

Table 7. Fault Response Functional Modes

EN/UVLO	RETRY_DLY	NRETRY	DEVICE STATE
L	X	X	Disabled
H	Short to GND	X	No auto-retry (Latch-off)
H	Open	Open	Auto-retry 4 times with minimum delay between retries and then latch-off
H	Open	Short to GND	Auto-retry indefinitely with minimum delay between retries
H	Capacitor to GND	Capacitor to GND	Auto-retry delay and count as per Equation 10 and Equation 11

Table 7. Fault Response Functional Modes (continued)

EN/UVLO	RETRY_DLY	NRETRY	DEVICE STATE
H	Capacitor to GND	Open	Auto-retry 4 times with finite delay between retries as per Equation 10 and then latch-off
H	Capacitor to GND	Short to GND	Auto-retry indefinitely with finite delay between retries as per Equation 10

Refer to *Fault Response* section for more details.

9 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

The TPS25982 device is an integrated 15-A eFuse that is typically used for hot-swap and power rail protection applications. It operates from 2.7 V to 24 V with adjustable overcurrent and undervoltage protection. It also provides optional overvoltage with various fixed internal thresholds. The device aids in controlling the inrush current and has the flexibility to configure the number of auto-retries and retry delay. The adjustable overcurrent blanking timer provides the functionality to allow transient overcurrent pulses without limiting or tripping. These devices protect source, load and internal MOSFET from potentially damaging events in systems such as Server standby rails, PCIe cards, SSDs, HDDs, Optical Modules, Routers and Switches.

The following design procedure can be used to select the supporting component values based on the application requirement. Additionally, a spreadsheet design tool *TPS25982xx Design Calculator* is available in the web product folder.

9.2 Typical Application: Standby Power Rail Protection in Datacenter Servers

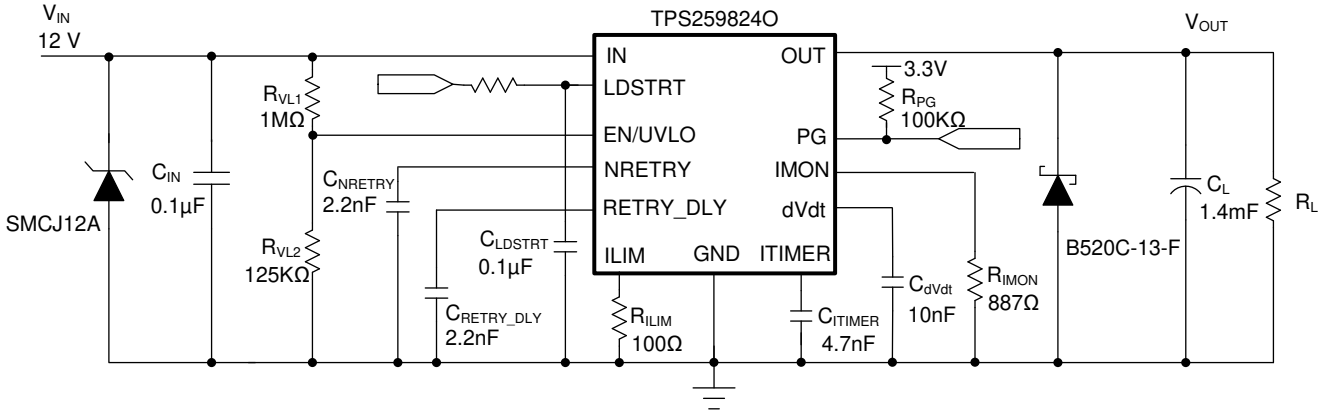

Figure 52. Typical Application Schematic - Protection for Server Standby Rail

9.2.1 Design Requirements

Table 8 shows the design parameters for this application example.

Table 8. Design Parameters

DESIGN PARAMETER	EXAMPLE VALUE
Input voltage, V_{IN}	12 V
Undervoltage lockout set point, VIN_{UVLO}	10.8 V
Maximum load current, I_{OUT}	12 A
Current limit, I_{LIM}	15 A
Transient overcurrent blanking interval (t_{ITIMER})	2 ms
Load capacitance, C_{OUT}	1.4 mF
Load at start-up, $R_{L(SU)}$	10 Ω
Output voltage ramp time, T_{dVdt}	20 ms
Maximum ambient temperature, T_A	70 °C

Typical Application: Standby Power Rail Protection in Datacenter Servers (continued)

Table 8. Design Parameters (continued)

LDSTRT handshake delay, t_{LDSTRT}	60 ms
Retry delay, t_{RETRY_DLY}	100 ms
No. of retries, N_{RETRY}	4

9.2.2 Detailed Design Procedure

9.2.2.1 Device Selection

This design example considers a 12-V system operating voltage with a tolerance of ±10 %. The rated load current is 12 A. If the current exceeds 15 A, then the device must allow overload current for 2-ms interval before breaking the circuit and then restart. Accordingly, the TPS259824O variant is chosen. (Refer to *Device Comparison Table* for device options.) Ambient temperatures may range from 20 °C to 70 °C. The load has a minimum input capacitance of 1.4 mF and start-up resistive load of 10 Ω. The downstream load is turned on only after the PG signal is asserted.

9.2.2.2 Setting the Current Limit Threshold: R_{ILIM} Selection

The R_{ILIM} resistor at the ILIM pin sets the overload current limit, whose value can be calculated using Equation 12.

$$R_{ILIM}(\Omega) = \frac{1460}{I_{LIM}(A) - 0.11} \tag{12}$$

For I_{LIM} = 15 A, R_{ILIM} value is calculated to be 98.05 Ω. Choose the closest available standard value: 100 Ω, 1%. Refering to the Electrical Characteristics table, it can be verified that the minimum current limit across temperature for R_{ILIM} value of 100 Ω is 12.85 A, which is higher than the nominal rated load current (12 A), thereby ensuring stable operation under normal conditions.

9.2.2.3 Setting the Undervoltage Lockout Set Point

The undervoltage lockout (UVLO) trip point is adjusted using the external voltage divider network of R_{VL1} and R_{VL2} connected between IN, EN/UVLO and GND pins of the device. The resistor values required for setting the undervoltage are calculated using Equation 13.

$$VIN_{UVLO} = \frac{V_{UVLO(R)} \times (R_{VL1} + R_{VL2})}{R_{VL2}} \tag{13}$$

For minimizing the input current drawn from the power supply, TI recommends to use higher values of resistance for R_{VL1} and R_{VL2}. However, leakage currents due to external active components connected to the resistor string can add error to these calculations. So, the resistor string current, I_{RVL12} must be 20 times greater than the leakage current (I_{ENLKG}).

From the device electrical specifications, UVLO rising threshold $V_{UVLO(R)}$ = 1.2 V. From design requirements, VIN_{UVLO} = 10.8 V. First choose the value of R_{VL1} = 1 MΩ and use Equation 13 to calculate R_{VL2} = 125 kΩ.

Use the closest standard 1% resistor values: R_{VL1} = 1 MΩ, and R_{VL2} = 125 kΩ

9.2.2.4 Choosing the Current Monitoring Resistor: R_{IMON}

Voltage at IMON pin V_{IMON} is proportional to the output load current. This can be connected to an ADC of the downstream system for monitoring the operating condition and health of the system. The R_{IMON} must be selected based on the maximum load current and the maximum IMON pin voltage at full-scale load current. The maximum IMON pin voltage must be selected based on the input voltage range of the ADC used or the value suggested in *VIMON(Max) Recommended Values*, whichever is lower. R_{IMON} is set using Equation 14.

$$R_{IMON}(\Omega) = \frac{V_{IMONmax}(V)}{I_{OUTmax}(A) \times 246 \times 10^{-6}} \tag{14}$$

For I_{LIM} = 15 A and considering the operating range of ADC to be 0 V to 3.3 V, R_{IMON} can be calculated as

$$R_{IMON} = \frac{3.3}{15 \times 246 \times 10^{-6}} = 894\ \Omega \quad (15)$$

Selecting R_{IMON} value less than shown in Equation 15 ensures that ADC limits are not exceeded for maximum value of load current. Choose closest available standard value: 887 Ω, 1 %.

9.2.2.5 Setting the Output Voltage Ramp Time (T_{dVdt})

For a successful design, the junction temperature of device must be kept below the absolute maximum rating during both dynamic (start-up) and steady state conditions. Dynamic power stresses often are an order of magnitude greater than the static stresses, so it is important to determine the right start-up time and in-rush current limit required with system capacitance to avoid thermal shutdown during start-up with and without load.

The required ramp-up capacitor C_{dVdt} is calculated considering the two possible cases (see *Case 1: Start-Up Without Load: Only Output Capacitance C_{OUT} Draws Current* and *Case 2: Start-Up With Load: Output Capacitance C_{OUT} and Load Draw Current*)

9.2.2.5.1 Case 1: Start-Up Without Load: Only Output Capacitance C_{OUT} Draws Current

During start-up, as the output capacitor charges, the voltage drop as well as the power dissipated across the internal FET decreases. The average power dissipated in the device during start-up is calculated using Equation 16

$$P_{D(INRUSH)} = 0.5 \times V_{IN} \times I_{INRUSH} \quad (16)$$

Where I_{INRUSH} is the inrush current and is determined by Equation 17

$$I_{INRUSH} = C_{OUT} \times \frac{V_{IN}}{T_{dVdt}} \quad (17)$$

Equation 16 assumes that the load does not draw any current (apart from the capacitor charging current) until the output voltage has reached its final value.

9.2.2.5.2 Case 2: Start-Up With Load: Output Capacitance C_{OUT} and Load Draw Current

When the load draws current during the turn-on sequence, there is additional power dissipated. Considering a resistive load during start-up $R_{L(SU)}$, load current ramps up proportionally with increase in output voltage during T_{dVdt} time. Equation 18 shows the average power dissipation in the internal FET during charging time due to resistive load.

$$P_{D(LOAD)} = \left(\frac{1}{6}\right) \times \frac{V_{IN}^2}{R_{L(SU)}} \quad (18)$$

Equation 19 gives the total power dissipated in the device during start-up

$$P_{D(STARTUP)} = P_{D(INRUSH)} + P_{D(LOAD)} \quad (19)$$

The power dissipation, with and without load, for selected start-up time must not exceed the start-up thermal shutdown limits as shown in *Thermal Shutdown Plot During Start-up*

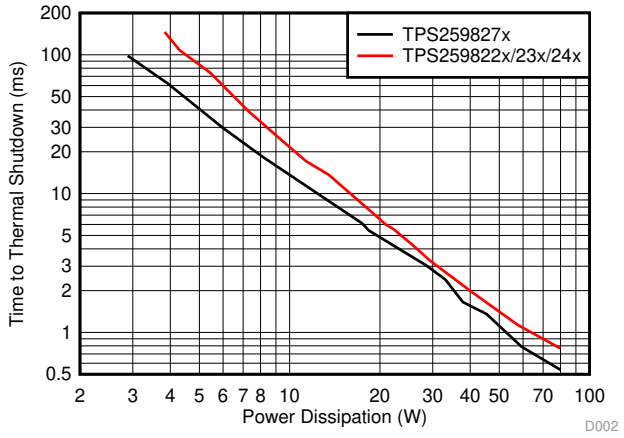

Figure 53. Thermal Shutdown Plot During Start-up

For the design example under discussion, the output voltage has to be ramped up in 20 ms, which mandates a slew-rate of 0.6 V/ms for a 12 V rail.

The required C_{dVdt} capacitance on dVdt pin to set 0.6 V/ms slew rate can be calculated using Equation 20

$$C_{dVdt}(pF) = \frac{4600}{SR(V/ms)} = 7666\ pF \tag{20}$$

The dVdt capacitor is subjected to typically V_{IN}+ 4 V during startup. The high voltage bias leads to a drop in the effective capacitor value. So, it is suggested to choose 20% higher than the calculated value, which gives 9.2 nF. Choose closest 10% standard value: 10 nF

The 10 nF C_{dVdt} capacitance sets a slew-rate of 0.46 V/ms and output ramp time T_{dVdt} of 26 ms.

The inrush current drawn by the load capacitance C_{OUT} during ramp-up can be calculated using Equation 21

$$I_{INRUSH} = 1.4\ mF \times \frac{12\ V}{26\ ms} = 0.65\ A \tag{21}$$

The inrush power dissipation can be calculated using Equation 22

$$P_{D(INRUSH)} = 0.5 \times 12 \times 0.65 = 3.9\ W \tag{22}$$

For 3.9 W of power loss, the thermal shutdown time of the device must be greater than the ramp-up time T_{dVdt} to ensure a successful start-up. *Figure 53* shows the start-up thermal shutdown limit. For 3.9 W of power, the shutdown time is approximately 100 ms. So it is safe to use 26 ms as the start-up time without any load on the output.

The additional power dissipation when a 10-Ω load is present during start-up is calculated using Equation 23

$$P_{D(LOAD)} = \left(\frac{1}{6}\right) \times \frac{12^2}{10} = 2.4W \tag{23}$$

The total device power dissipation during start-up can be calculated using Equation 24

$$P_{D(STARTUP)} = 3.9 + 2.4 = 6.3\ W \tag{24}$$

From *Thermal Shutdown Plot During Start-up*, the thermal shutdown time for 6.3 W is approximately 40 ms. It is safe to have 30% margin to allow for variation of system parameters such as load, component tolerance, and input voltage. So it is well within acceptable limits to use the 10 nF for C_{dVdt} capacitor with start-up load of 10 Ω.

When C_{OUT} is large, there is a need to decrease the power dissipation during start-up. This can be done by increasing the value of the C_{dVdt} capacitor. A spreadsheet tool *TPS25982xx Design Calculator* available on the web can be used for iterative calculations.

9.2.2.6 Setting the Load Handshake (LDSTRT) Delay

To indicate a successful start-up, the load circuit must provide a handshake signal to TPS25982 by pulling down the LDSTRT pin within the time set by the capacitor C_{LDSTRT} on the LDSTRT pin. Once the PG asserts, the device sources 2-µA current into C_{LDSTRT}. For a successful handshake, the load circuit must pull-down the LDSTRT pin before C_{LDSTRT} charges up to 1.2 V.

For the design requirement of 60-ms handshake delay, use Equation 25 to calculate C_{LDSTRT}

$$C_{LDSTRT} = I_{LDSTRT} \times \frac{t_{LDSTRT}}{V_{LDSTRT}} = 2\mu A \times \frac{60ms}{1.2V} = 0.1\mu F \quad (25)$$

Choose closest available standard value: 0.1 µF, 10 %.

9.2.2.7 Setting the Transient Overcurrent Blanking Interval (t_{ITIMER})

For the design example under discussion, overcurrent transients are allowed for 2-ms duration. This blanking interval can be set by selecting appropriate capacitor C_{ITIMER} from ITIMER pin to ground. The value of C_{ITIMER} to set 2 ms for t_{ITIMER} can be calculated using Equation 26.

$$C_{ITIMER}\,(nF) = \frac{t_{ITIMER}\,(ms)}{0.47} = 4.255\ nF \quad (26)$$

Choose closest available standard value: 4.7 nF, 10 %.

9.2.2.8 Setting the Auto-Retry Delay and Number of Retries

The time delay between retries can be programmed by selecting capacitor C_{RETRY_DLY} on RETRY_DLY pin. The value of C_{RETRY_DLY} to set a 100-ms auto-retry delay can be calculated using Equation 27.

$$C_{RETRY\_DLY}\,(pF) = \frac{t_{RETRY\_DLY}\,(\mu s)}{46.83} - 4\ pF = 2131.38\ pF \quad (27)$$

Choose closest available standard value: 2.2 nF, 10 %.

The number of auto-retry attempts can be set by a capacitor C_{NRETRY} on the NRETRY pin using Equation 28

$$N_{RETRY} = \frac{4 \times C_{NRETRY}\,(pF)}{C_{RETRY\_DLY}\,(pF) + 4\ pF} \quad (28)$$

For this design example, the requirement is to retry 4 times after the device shuts down due to a fault. Since, the number of auto-retries can be adjusted in discrete steps as explained in *Fault Response* , choose C_{NRETRY} such that N_{RETRY} is less than 4. Use Equation 29 to calculate C_{NRETRY}.

$$C_{NRETRY}\,(pF) < \frac{N_{RETRY} \times \left(C_{RETRY\_DLY}\,(pF) + 4\ pF\right)}{4} < 2204\ pF \quad (29)$$

Choose closest available standard value: 2.2 nF, 10 %.

9.3 System Examples

9.3.1 Optical Module Power Rail Path Protection

Optical modules are commonly used in high-bandwidth data communication systems such as Optical Networking equipment, Enterprise/Data-Center Switches and Routers. Several variants of optical modules are available in the market, which differ in the form-factor and the data speed support (Gbit/s). Of these, the popular variant Double Dense Quad Small Form-factor Pluggable (QSFP-DD) module supports speeds up to 400 Gbit/s. In addition to the system protection during hot-plug events, the other key requirement for optical module is the tight voltage regulation. The optical module uses 3.3 V supply and requires voltage regulation within ±5 % for proper operation.

A typical power tree of such system is shown in Figure 64. The optical line card consists of DC-DC converter, protection device (eFuse) and power supply filters. The DC-DC converter steps-down the 12 V to 3.3 V and maintains the 3.3 V rail within ±2 %. The power supply filtering network uses 'LC' components to reduce high frequency noise injection into the optical module. The DC resistance of the inductor 'L' causes voltage drop of around 1.5 % which leaves us with a voltage drop budget of just 1.5 % (3.3 V * 1.5% = 50 mV) across the protection device. Considering a maximum load current of 5.5 A per module, the maximum ON-resistance of the protection device should be less than 9 mΩ. TPS25982 eFuse offers ultra-low ON-resistance of 2.7 mΩ (typical) and 4.5 mΩ (maximum, across temperature), thereby meeting the target specification with additional margin to spare and simplifying the overall system design.

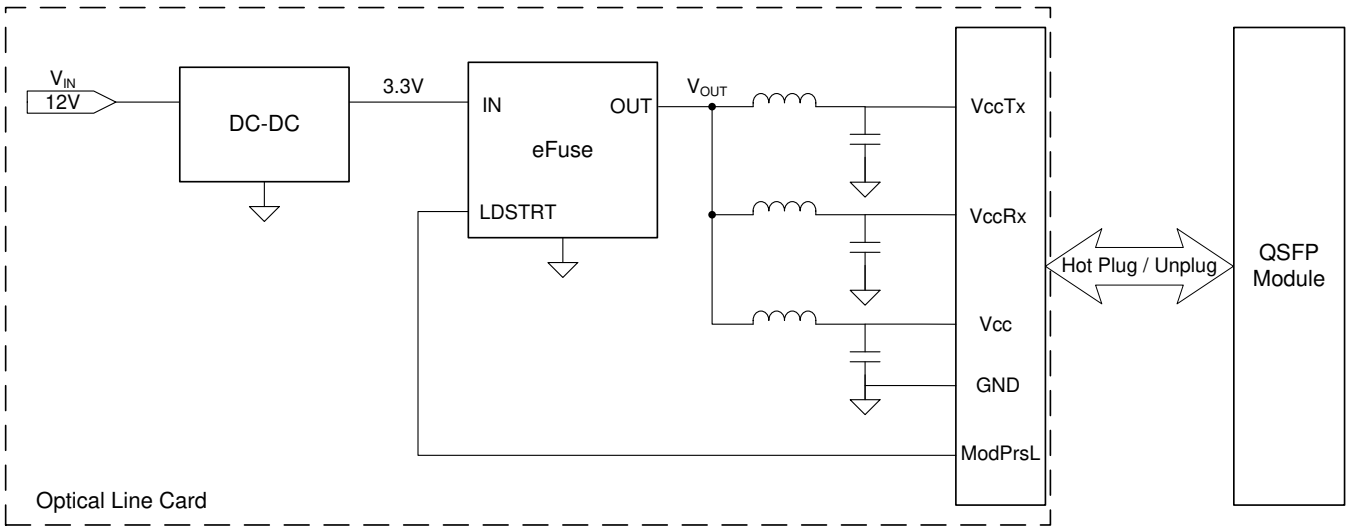

Figure 64. Power Tree Block Diagram of a Typical Optical Line Card

As shown in *Figure 64*, ModPrsL signal acts as a handshake signal between the line card and the optical module. ModPrsL is always pulled to ground inside the module. When the module is hot-plugged into the host "Optical Line Card" connector, the ModPrsL signal pulls down the LDSTRT pin and enables the TPS25982 eFuse to power the module. This ensures that power is applied on the port only when a module is plugged in and disconnected when there is no module present.

System Examples (continued)

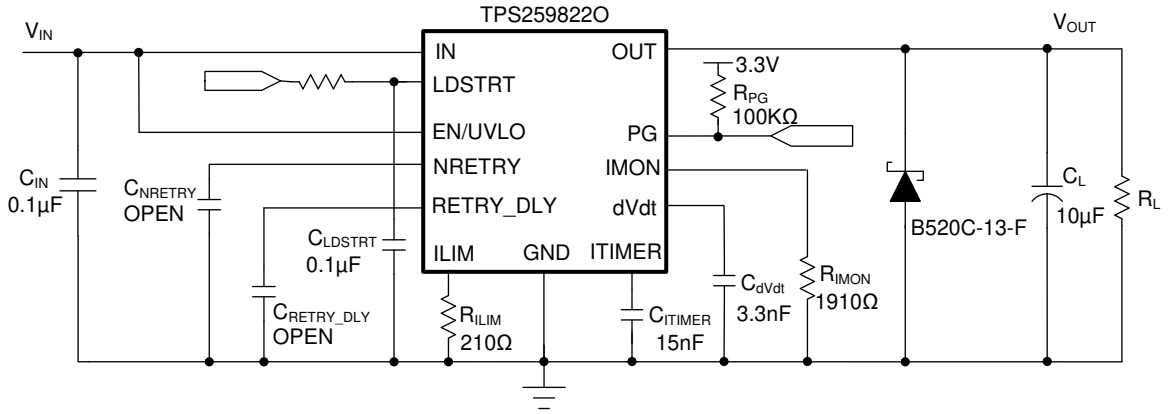

Figure 65. TPS259822O Configured for a 3.3-V Power Rail Path Protection in Optical Module

9.3.1.1 Design Requirements

Table 9 shows the design parameters for this example.

Table 9. Design Parameters

DESIGN PARAMETER	EXAMPLE VALUE
Input voltage, V_{IN}	3.3 V
Overvoltage lockout, V_{OVP}	3.7 V
Maximum voltage drop in the path	± 5 %
Maximum load current, I_{OUT}	5.5 A
Current limit, I_{LIM}	7 A
Transient overcurrent blanking interval (t_{ITIMER})	6 ms
Load capacitance, C_{OUT}	10 µF
Maximum ambient temperature, T_A	85 °C
Module present detection, ModPrsL	Yes
Retry delay, t_{RETRY_DLY}	200 µs
No. of retries, N_{RETRY}	4

9.3.1.2 Device Selection

Optical modules are very sensitive to supply voltage variations and thus require input overvoltage protection. TPS259822O variant from TPS25982 family is selected to set overvoltage protection at 3.7 V. TPS259822O allows overcurrents for a user specified blanking interval t_{ITIMER} before breaking the circuit path. In this use case, t_{ITIMER} is set for 6 ms interval.

9.3.1.3 External Component Settings

By following similar design procedure as outlined in *Detailed Design Procedure*, the external component values are calculated as below

- R_{ILIM} = 210 Ω to set 7-A current limit
- C_{ITIMER} = 15 nF to set fault blanking time of 6 ms
- R_{IMON} = 1910 Ω to set maximum IMON pin voltage V_{IMON} within ADC range of 3.3 V
- C_{dVdt} capacitance is chosen as 3.3 nF
- Leave RETRY_DLY and NRETRY pins OPEN to set minimum auto-retry delay of 200 µs and number of retries to 4

9.3.1.4 Voltage Drop

Table 10 shows the power path voltage drop (%) due to the eFuse in QSFP modules of different power classes.

Table 10. Voltage Drop across TPS25982 on QSFP Module Power Rail

POWER CLASS	MAXIMUM POWER CONSUMPTION PER MODULE (W)	MAXIMUM LOAD CURRENT (A)	TYPICAL VOLTAGE DROP (%)
1	1.5	0.454	0.037
2	3.5	1.06	0.087
3	7	2.12	0.174
4	8	2.42	0.2
5	10	3.03	0.248
6	12	3.63	0.3
7	14	4.24	0.347
8	18	5.45	0.446

9.3.2 Input Protection for 12-V Rail Applications: PCIe Cards, Storage Interfaces and DC Fans

TPS25982 eFuse provides inrush current management and also protects the system from most common faults such as undervoltage, overvoltage and overcurrents. The combination of high current support along with low ON-resistance makes TPS25982 eFuse an ideal protection solution for PCIe cards, Storage Interfaces and DC Fan loads. The external component values can be calculated by following the design procedure outlined in *Detailed Design Procedure*. Alternatively, a spreadsheet design tool *TPS25982xx Design Calculator* is available for simplified design efforts.

10 Power Supply Recommendations

The TPS25982 devices are designed for a supply voltage range of 2.7 V ≤ VIN ≤ 24 V. TI recommends an input ceramic bypass capacitor higher than 0.1 µF if the input supply is located more than a few inches from the device. The power supply must be rated higher than the set current limit to avoid voltage droops during overcurrent and short-circuit conditions.

10.1 Transient Protection

In the case of a short circuit and overload current limit when the device interrupts current flow, the input inductance generates a positive voltage spike on the input, and the output inductance generates a negative voltage spike on the output. The peak amplitude of voltage spikes (transients) is dependent on the value of inductance in series to the input or output of the device. Such transients can exceed the absolute maximum ratings of the device if steps are not taken to address the issue. Typical methods for addressing transients include:

- Minimize lead length and inductance into and out of the device.
- Use a large PCB GND plane.
- Use a Schottky diode across the output to absorb negative spikes.
- Use a low value ceramic capacitor C_{IN} = 0.001 µF to 0.1 µF to absorb the energy and dampen the transients. The approximate value of input capacitance can be estimated using Equation 30.

$$V_{SPIKE(Absolute)} = V_{IN} + I_{LOAD} \times \sqrt{\frac{L_{IN}}{C_{IN}}} \quad (30)$$

where

- V_{IN} is the nominal supply voltage
- I_{LOAD} is the load current
- L_{IN} equals the effective inductance seen looking into the source
- C_{IN} is the capacitance present at the input

Some of the applications may require the addition of a Transient Voltage Suppressor (TVS) to prevent transients from exceeding the absolute maximum ratings of the device. A typical circuit implementation with optional protection components (a ceramic capacitor, TVS and Schottky diode) is shown in Figure 72.

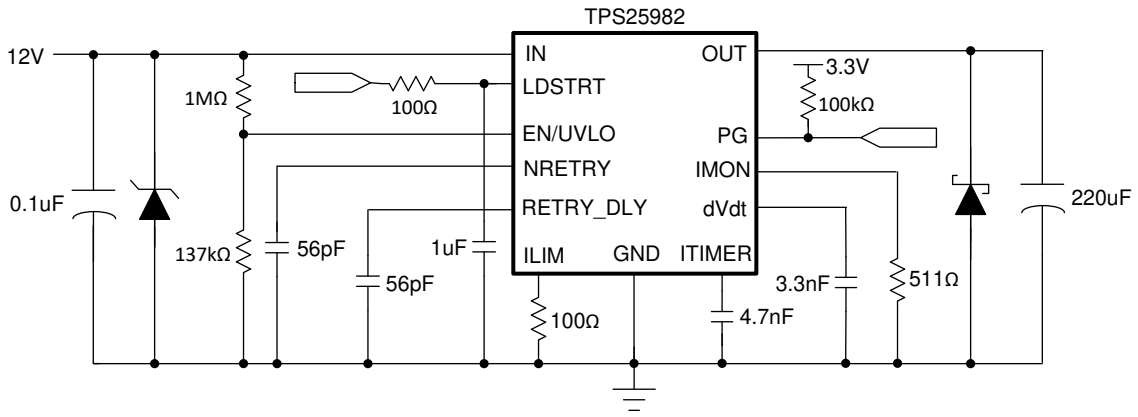

Figure 72. Typical Circuit Implementation With Optional Protection Components

10.2 Output Short-Circuit Measurements

It is difficult to obtain repeatable and similar short-circuit testing results. The following contribute to variation in results:

- Source bypassing
- Input leads
- Board layout
- Component selection
- Output shorting method
- Relative location of the short
- Instrumentation

The actual short exhibits a certain degree of randomness because it microscopically bounces and arcs. Ensure that configuration and methods are used to obtain realistic results.

NOTE

Do not expect to see waveforms exactly like the waveforms in this data sheet because every setup is different.

11 Layout

11.1 Layout Guidelines

- The IN Exposed Thermal Pad is used for Heat Dissipation. Connect to as much copper area as possible using an array of thermal vias. The via array also helps to minimize the voltage gradient across the VIN pad and facilitates uniform current distribution through the internal FET, which improves the current sensing and monitoring accuracy.
- For all applications, TI recommends a ceramic decoupling capacitor of 0.01 μF or greater between IN and GND terminals. For hot-plug applications, where input power-path inductance is negligible, this capacitor can be eliminated or minimized.
- The optimal placement of the decoupling capacitor is closest to the IN and GND terminals of the device. Care must be taken to minimize the loop area formed by the bypass-capacitor connection, the IN terminal, and the GND terminal of the IC.
- High current carrying power path connections must be as short as possible and must be sized to carry at least twice the full-load current. It is recommended to use a minimum trace width of 50 mil for the OUT power connection.
- The GND terminal is the reference for all internal signals and must be isolated from any bounce due to large switching currents in the system power ground plane. It is recommended to connect the device GND to a signal ground island on the board, which in turn is connected to the system power GND plane at one point.
- Locate the support components for the following signals close to their respective connection pins - ILIM, IMON, ITIMER, RETRY_DLY, NRETRY and dVdT with the shortest possible trace routing to reduce parasitic effects on the respective associated functions. These traces must not have any coupling to switching signals on the board.
- The ILIM pin is highly sensitive to capacitance and TI recommends to pay special attention to the layout to maintain the parasitic capacitance below 30 pF for stable operation.
- Use short traces on the RETRY_DLY and NRETRY pins to ensure the auto-retry timer delay and number of auto-retries is not altered by the additional parasitic capacitance on these pins.
- Protection devices such as TVS, snubbers, capacitors, or diodes must be placed physically close to the device they are intended to protect. These protection devices must be routed with short traces to reduce inductance. For example, TI recommends a protection Schottky diode to address negative transients due to switching of inductive loads, and it must be physically close to the OUT pins.
- Use proper layout and thermal management techniques to ensure there is no significant steady state thermal gradient between the two thermal pads on the IC. This is necessary for proper functioning of the device overtemperature protection mechanism and successful startup under all conditions.
- Obtaining acceptable performance with alternate layout schemes is possible; the *Layout Example* is intended as a guideline and shown to produce good results from electrical and thermal standpoint.

12.2 Receiving Notification of Documentation Updates

To receive notification of documentation updates, navigate to the device product folder on ti.com. In the upper right corner, click on *Alert me* to register and receive a weekly digest of any product information that has changed. For change details, review the revision history included in any revised document.

12.3 Community Resources

TI E2E™ support forums are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's Terms of Use.

12.4 Trademarks

E2E is a trademark of Texas Instruments.

12.5 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

(1) **Status:** For more details on status, see our product life cycle.

(2) **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

(3) **RoHS values:** Yes, No, RoHS Exempt. See the TI RoHS Statement for additional information and value definition.

(4) **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

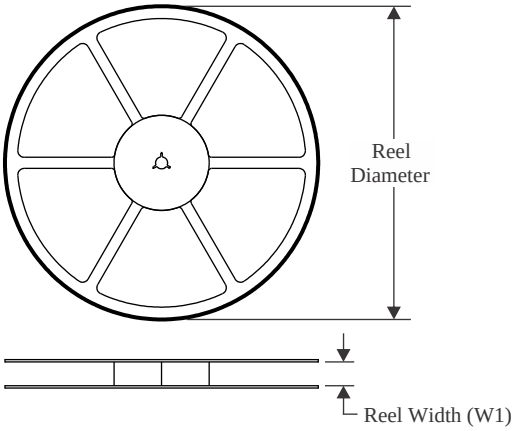
(5) **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

(6) **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

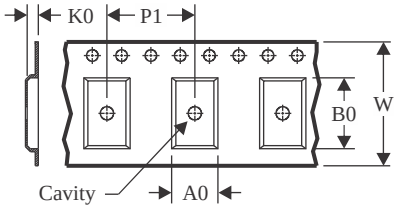
Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

TAPE AND REEL INFORMATION

REEL DIMENSIONS

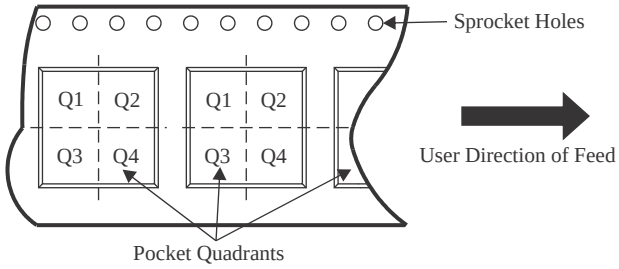


TAPE DIMENSIONS



A0	Dimension designed to accommodate the component width
B0	Dimension designed to accommodate the component length
K0	Dimension designed to accommodate the component thickness
W	Overall width of the carrier tape
P1	Pitch between successive cavity centers

QUADRANT ASSIGNMENTS FOR PIN 1 ORIENTATION IN TAPE



*All dimensions are nominal

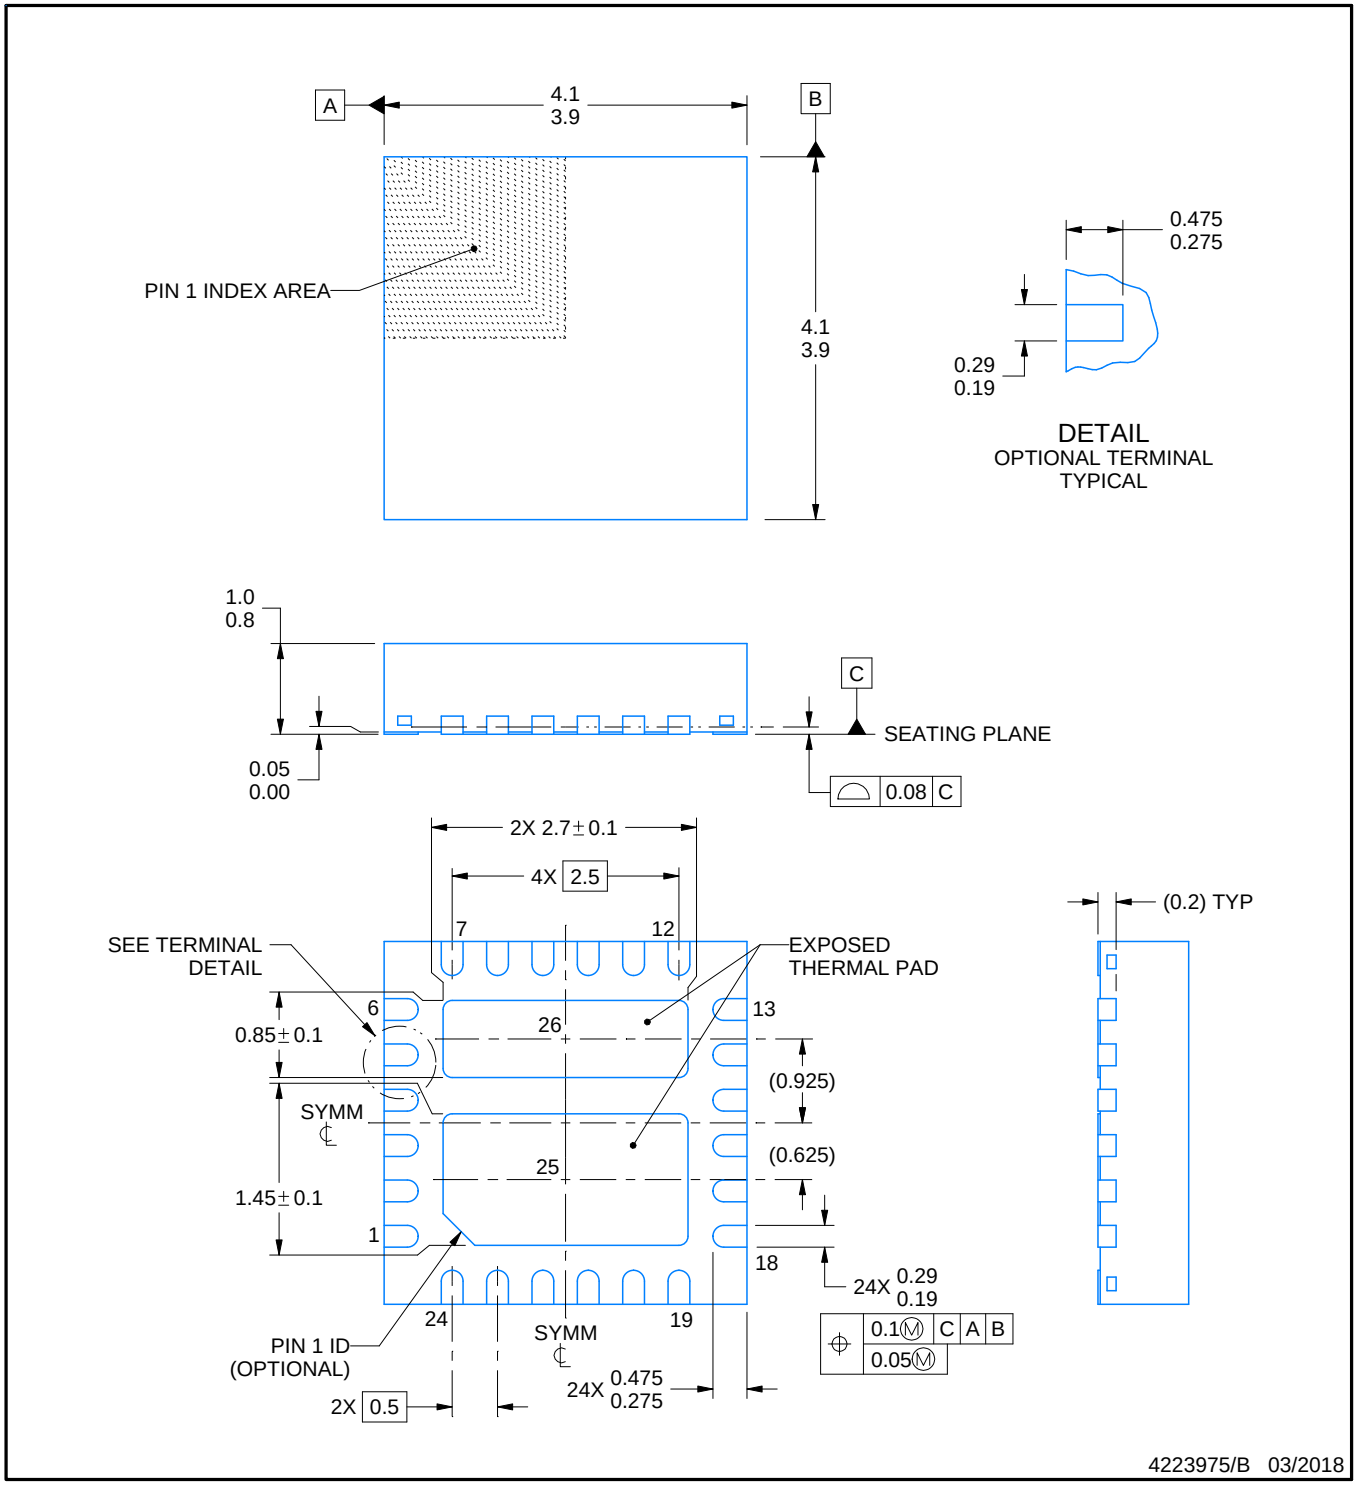
PACKAGE OUTLINE

RGE0024M

VQFN - 1 mm max height

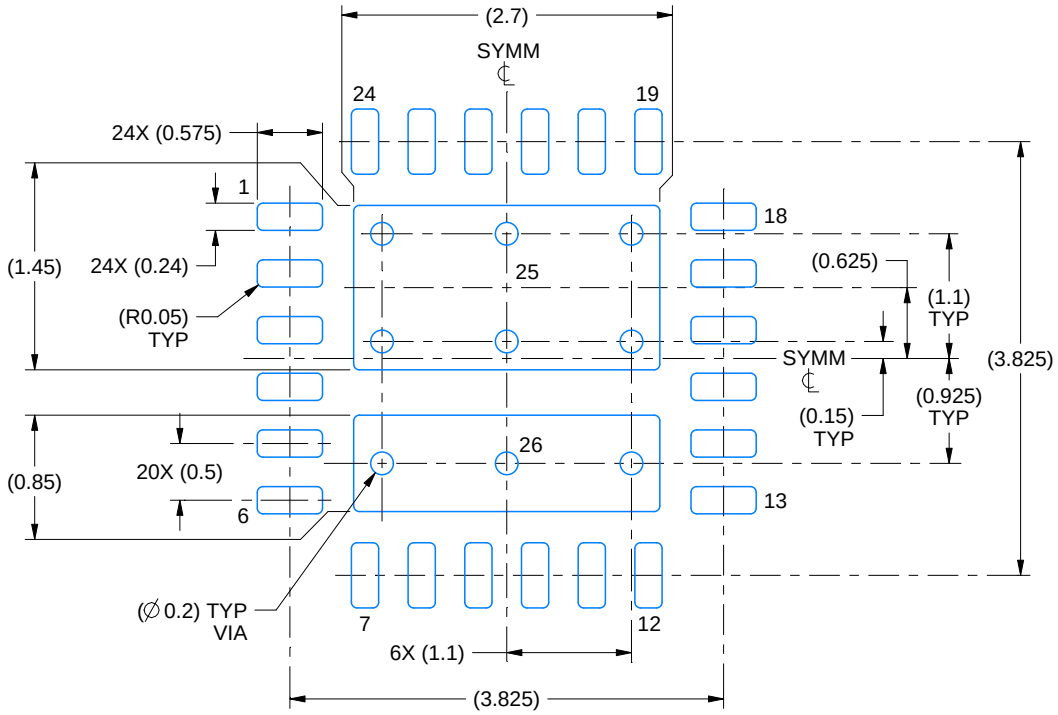
PLASTIC QUAD FLATPACK - NO LEAD



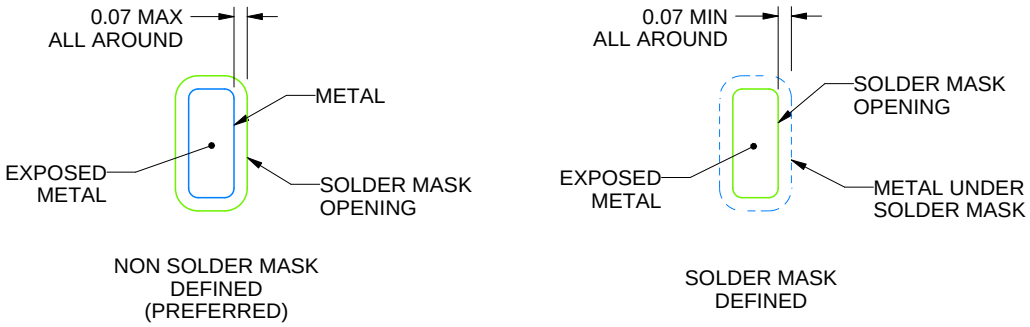
4223975/B 03/2018

NOTES:

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. The package thermal pad must be soldered to the printed circuit board for thermal and mechanical performance.



LAND PATTERN EXAMPLE
EXPOSED METAL SHOWN
SCALE:15X

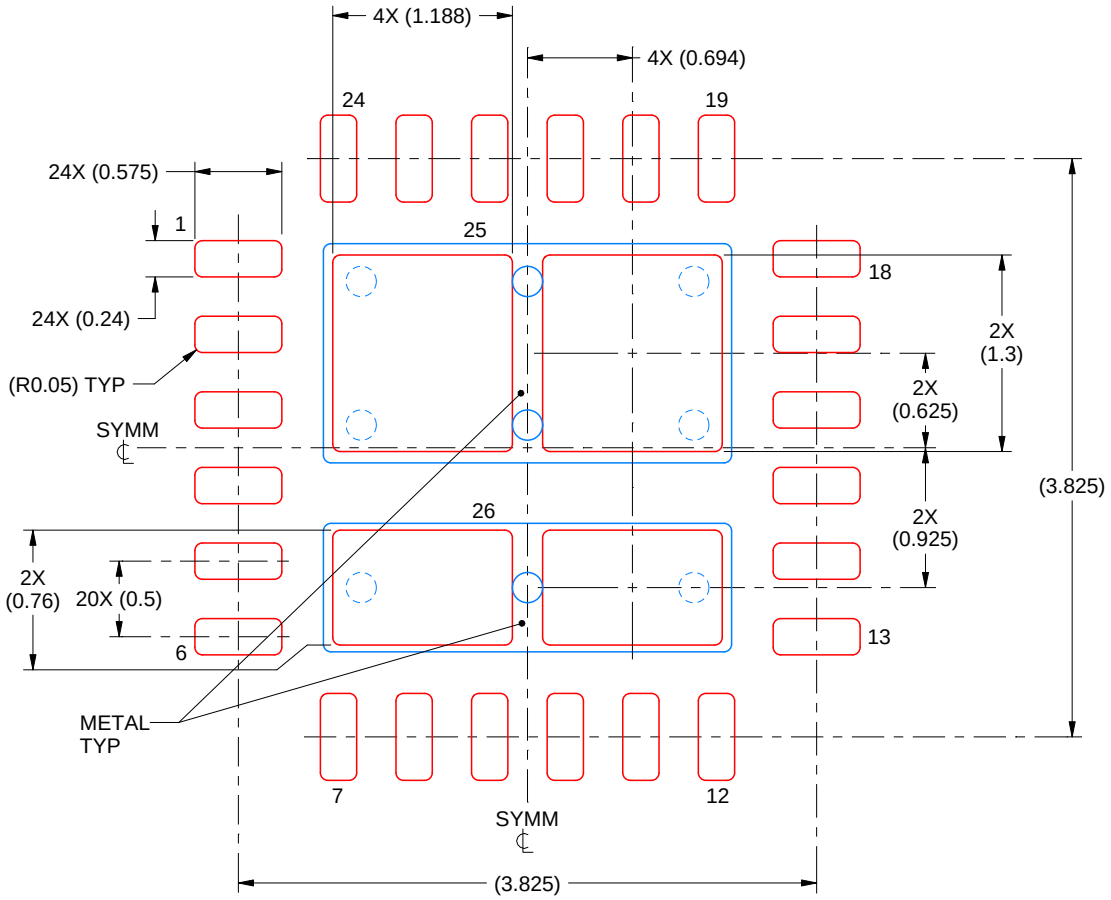


SOLDER MASK DETAILS

4223975/B 03/2018

NOTES: (continued)

4. This package is designed to be soldered to a thermal pad on the board. For more information, see Texas Instruments literature number SLUA271 (www.ti.com/lit/slua271).
5. Vias are optional depending on application, refer to device data sheet. If any vias are implemented, refer to their locations shown on this view. It is recommended that vias under paste be filled, plugged or tented.



SOLDER PASTE EXAMPLE
BASED ON 0.125 mm THICK STENCIL

EXPOSED PAD 25
78% PRINTED SOLDER COVERAGE BY AREA UNDER PACKAGE
SCALE:20X

4223975/B 03/2018

NOTES: (continued)

6. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.
